IN his recent presidential address to the Royal Society of Edinburgh on "Some Disputed Questions in the Philosophy of the Physical Sciences", Prof. E. T. Whittaker discussed the problem raised by the Greeks and at the present time vigorously debated by Eddington, Jeffreys, Milne, Jeans, Dingle and others, on the respective shares of reason and observation in the discovery of the laws of Nature. He recalled that the Greeks considered that geometry could be built up completely apart from observation, but that Aristotle at least (and much later Aquinas) held that other sciences must be built on experience. Later progress showed that geometry also must be regarded as a branch of experimental knowledge, and from the time of Newton until now, the principle that science rests fundamentally on observation and experiment has been unchallenged. Now, however, certain thinkers—notably Milne and Eddington—hold that the laws of Nature can be derived without recourse to observation. Prof. Whittaker points out that many important branches of physics can be deduced from single "postulates of impotence" ; for example, the whole of relativity theory follows from the postulate that it is impossible to detect absolute motion. Such postulates are not the direct result of experiment, though they are generalizations from experiment. Milne's "cosmological principle" is in form a postulate of impotence, but it is assumed without experimental support. Eddington's "epistemological principles", however, are different, but Prof. Whittaker is not convinced that they have any basis outside experience. His verdict on Eddington's claim is : "Not Proven".

The concentration into postulates of impotence of the experimental contribution to physical laws is a very suggestive generalization, and it is an interesting conjecture that the whole of physical law might ultimately be derived by reason from a single postulate of impotence. At the same time it would be a mistake to suppose that anything significant can come out of a pure negation. A postulate of impotence is indebted to experience not only for failure to violate it but also for an indication of the positive thing which in the stated circumstances it denies. The impossibility of spontaneous passage of heat from cold to hot bodies implies the fact of experience that heat can pass between bodies ; the denial of absolute motion would be without meaning if we had no experience of relative motion ; and so on. It is a pity that Prof. Whittaker's address was prepared before Eddington's recent change of front. In the "Philosophy of Physical Science" he wrote : "For the truth of the conclusions of physical science, observation is the supreme Court of Appeal" (p. 9), and accepted the statement that physics is "the rational correlation of experience" (p. 185). In NATURE of October 25, 1941, however, he stated, in reply to the objection that the supreme Court of Appeal might decide against the rationally derived laws, that "the fundamental ('inviolable') laws are not assertions about experience". It appears, therefore that Prof. Whittaker has been analysing a superseded claim.

Science as a Force of Freedom

THE value of science as a force of freedom was emphasized by Mr. G. B. Lal in a recent address to the New History Society, New York. The power of science is unique. Great men of science have world-wide influence. But they have achieved such influence without the use of the slightest violence or fraud. People have killed each other for religion ; but not for science. In science there is a peculiar and most important pattern of freedom. Science develops only when the scientific worker has enough social power to enable him to do his work utterly unhampered. Also, every development in science releases new forms of social energy. Most people respect science because of its practical importance, as shown by the machines of scientific inventors, the conquest of diseases, the piling up of profits in industries, the production of military weapons, rapid transportation and communication. But the most important thing about science is its method. The scientific method is the most efficient use of human intelligence for the discovery of truth.

Physics of a Transmission Line

PROF. W. M. THORNTON has published a thought-provoking paper with the above title (*J. Inst. Elec. Eng.*, **88**, Pt. II, No. 6, Dec., 1941) in which he deals with the fundamental and, in part, unknown field of electromagnetic study underlying the many technical and economic problems entailed in the design, construction and operation of electric transmission lines. He pays special attention to the electromagnetic mechanism by which electric and magnetic stresses in space combine so that the energy of electric strain passes continuously along the insulating medium around the wires. Remarking that this, the Poynting flux flow, is the least known of the physical actions in transmission, Prof. Thornton discusses the transfer of potential energy along a transmission line by strain of the insulation, extending the theory to the supply of energy to electric lamps, heaters and rotating machinery. Following a lucid explanation of Poynting's theorem, physical analogies are given to the resistance, inductance and capacitance of a transmission line, resistance being regarded as the coefficient of dissipation of energy, inductance as inertia, and capacitance as elasticity ; an invisible shaft of energy which would be perfectly rigid in the absence of inductance and capacitance rotates about the conductors of a three-phase system at the supply frequency.

Suggesting that there may still be engineers who regard the purity of the copper of their machines or cables as more important than insulation quality, the paper proceeds to a discussion of the function of insulation and the complex nature of corona, pointing out the limiting influence of the latter on voltage, while emphasizing that from the same aspect moisture effects are more important than corona. Prof. Thornton closes with a brief mention of the mechanical design of insulators, remarking that the complex physical stresses, electrical and mechanical, in a suspension insulator form a difficult three-dimensional problem which may well repay further investigation.

Technical Developments in Broadcasting

IN his chairman's address to the Wireless Section of the Institution of Electrical Engineers (*J. Inst. Elec. Eng.*, 89, Pt. 1, No. 13; 1942) H. Bishop of the B.B.C., in reviewing the general trend of progress up to the outbreak of hostilities, gave first an outline of the underlying principles involved in the acoustic design of studios and mentioned some of the difficulties associated with the microphone. Programme input equipment and the control and measurement of the volume of broadcast programmes were discussed, special mention being made of the war-time application of sound recording and reproduction by the B.B.C. Tribute was paid to the Post Office in connexion with the use of telephone networks as music, control and television circuits. Transmitter design, modulation and frequency control and power plant received considerable attention. The influence of ionospheric storms on short-wave propagation was discussed, and a section included on the application and control of frequency measurement stations. The address closed with a reference to post-war receivers, suggesting that greater measures of standardization and reliability are needed to achieve the success so dependent on public interest.

Meteorology of Rhodesia

THE Meteorological Report of the Rhodesia Meteorological Service for the year ended June 30, 1940, has the signature of R. A. Jubb, acting chief meteorologist, owing to the appointment of the chief meteorologist, Mr. N. P. Sellick, to the post of deputy director of meteorological services of Southern Africa, with his headquarters at Pretoria. Since the period covered by the report includes the outbreak of war, to the normal activities of the service was added the work of reorganization to meet naval and military war-time requirements and the restrictions imposed by the censorship on the publication of weather reports and forecasts. In consequence of this handicap there are few new developments to record, but on the other hand the collection of meteorological statistics, including hourly readings of various instruments at the main observatories, was maintained without any general interruption, and continued to prove of great value to engineers and to various industrial enterprises. These statistics, in tabular form, occupy the greater part of the report. The addition of thermographs to many climatological stations was found to be useful both in tracing the travel of weather systems and as a check on the readings of thermometers. The seasonal forecast of the general rainfall by a formula taking into account the values of various meteorological elements at 'action centres' in distant regions was continued. A deficiency of 4·8 in. was predicted for 1939–40, but an excess of 3·3 in. was experienced. In the eleven years for which the results of such forecasts are available there were only two other comparable failures, whereas successful predictions were made in sever years, the most notable being an almost exact pre diction of the outstandingly heavy rainfall of 1938–39, which amounted to an excess of 12·2 in. compared witl the predicted excess of 11·8 in. The utility of these forecasts now appears to have been firmly established.

Social Implications of Dietetics

ADDRESSING the Rugby Branch of the Association of Scientific Workers on February 19 on the "Social Implications of Dietetics", Prof. V. H. Mottram examined the possibility of securing the basic dietetic essentials for healthy living in present circumstances. He stated that an investigation in Leicester as to the present cost of providing as close as possible an approximation to the British Medical Association estimate would be 11*s*. 3½*d*. per head per week. He compared with this the allowances being given for evacuated children and the dependants of Service men. Prof. Mottram suggested that only by special provision of family allowances on a fairly generous scale will it be possible to ensure that children will receive their needful intake of food essentials, and emphasized that the logic of free education leads on to the provision of free food for children and adolescents.

The future agricultural policy of Great Britain, Prof. Mottram said should be directed to growing more 'protective' foods—such as dairy foods and market garden produce—for which the soil and climate are best fitted. In this he was sustained by the agreement of Sir John Russell, Sir John Orr and Mr. A. G. Street. On the question of health in war-time, while pointing out that the tuberculosis-rate is rising, he agreed that there seems to be no deterioration and even some improvement in general health. This he attributed, not to any beneficial effects of rationing, but to better and more food being consumed by the millions now employed who have previously been unemployed, and by the millions now in the Army who are better fed than before. His conclusion was that little can be done in war-time to improve diet, though the provision of concentrates might be helpful.

Banana Research in Trinidad

PROF. C. W. WARDLAW, Barker professor of cryptogamic botany in the University of Manchester, read a paper on banana research in the Imperial College of Tropical Agriculture, Trinidad, at the Royal Society of Arts on February 24. After emphasizing the merits of the Jamaica banana or Gros Michel as a commercial variety, Prof. Wardlaw discussed its susceptibility to Panama disease, caused by the soil-borne fungus *Fusarium oxysporum cubense*. A three-fold research scheme to deal with this was organized by the College in collaboration with the Royal Botanic Gardens, Kew. Prof. Wardlaw then indicated some of the practical and scientific results obtained from this research scheme. Hybridization experiments and storage investigations were also described. Prof. Wardlaw was closely associated with these researches while on the staff of the Imperial College of Tropical Agriculture. Readers will recall the excellent series of three articles by him on the banana in Central America in NATURE (147, 313, 344, 380; 1941); and now they are recommended to read the present address, which covers the whole field and which will be published in due course in the *Journal of the Royal Society of Arts*.

Menace of Typhus

ACCORDING to an editorial in the *Medical Officer* of February 21, the prospect of typhus reaching Great Britain is more than likely, but the spread of the disease can be as certainly checked by extermination of lice as smallpox can be by vaccination. The distribution of typhus at the present time is mainly confined to Spain, North Africa and Eastern Europe. In October and November 1941 less than twenty cases a week were noted in the civil population of Germany. On the other hand, the article states that if the Russian counter-offensive becomes a rout and Germany is invaded, it would be impossible to prevent the disease spreading to the civil population of Germany and to all the occupied countries in Europe. Unless, however, the Germans invade Britain *en masse*, this country is not likely to be over-run by typhus. No case of typhus in Great Britain has been recorded for more than ten years, and there have been only rare and small outbreaks for the past half-century, in contrast with Ireland where there is an endemic focus in Connaught. The unlikelihood of the disease gaining a foothold in Great Britain is increased by the uncertainty of the head louse conveying the disease, the comparative rarity of body lice in our population and the comparative facility of body delousing.

University Grants

SIR KINGSLEY WOOD has announced in a written reply to a question in the House of Commons that the Government is to maintain its grant for 1942 to the universities at its existing level. He recalled that, in view of the vital part played by the universities in the life of the community, the importance of maintaining so far as possible standards of university education and the essential contribution of the universities towards the national effort, the Government decided early in 1941 to keep the universities grant at the 1939 and 1940 figure, namely, £2,149,000. The impact of the war on university finance has so far been less severe than was expected. On the other hand, while the repair of physical damage resulting from enemy action can be dealt with under the existing war damage legislation, the repair of war damage is by no means the only problem, involving large demands on university funds, which will arise on the conclusion of hostilities. In reaching a decision, the Government had in mind these points, and had also considered a report from the University Grants Committee reviewing the whole situation.

University of London

THE degree of D.Sc. has been conferred on the following: Dr. G. W. Scott Blair (National Institute for Research in Dairying); Dr. A. H. Cook (Imperial College of Science and Technology); Mr. C. L. Hewett (Royal Cancer Hospital (Free) and the Sir John Cass Technical Institute); Mr. Alexander King (Imperial College of Science and Technology); Mr. M. A. Phillips (Battersea Polytechnic); Dr. Eugene Rothstein (Imperial College of Science and Technology); Dr. Frank Smithson (Birkbeck College); Prof. F. R. Winton (University professor of pharmacology in University College).

The William Julius Mickle Fellowship has been awarded to Prof. Alexander Fleming, professor of bacteriology in St. Mary's Hospital Medical School.

Regulations have been adopted for the recently instituted certificate of proficiency in radio-physics.

Scholarships in Electrical Engineering

APPLICATIONS, which must be received not later than April 15, are invited for the following scholarships awarded by the Institution of Electrical Engineers (Savoy Place, London, W.C.2): *Duddell Scholarship* (value £150 per annum, tenable for three years): Open to British subjects under nineteen years of age on July 1, 1942, who have passed the matriculation examination of a British university or an examination exempting from matriculation and who wish to take up a whole-time day course in electrical engineering; *Silvanus Thompson Scholarship* (value £100 per annum and tuition fees, tenable for two years, renewable in approved cases for a third year): For works employees who are the sons of parents of limited means. Open to British subjects under twenty-two years of age on July 1, 1942, who (*a*) have served a minimum apprenticeship (or its equivalent) of three years at an approved electrical engineering works, and (*b*) in addition to having taken full advantage of available opportunities for technical education, have acquired a marked degree of skill, and/or shown evidence of originality. The successful candidate will be required to take up a whole-time day course in electrical engineering at an approved university or technical college; *William Beedie Esson Scholarship* (value £120 per annum, tenable for two years, renewable in approved cases for a third year): For works employees who are the sons of parents of limited means. Open to British subjects under twenty-two years of age on July 1, 1942, who have served a minimum apprenticeship (or its equivalent) of three years at an approved electrical engineering works. The successful candidate will be required to take up a whole-time day course in electrical engineering at an approved university or technical college.

Announcements

THE Medical Research Council has appointed Prof. A. W. M. Ellis, formerly University professor of medicine at the London Hospital, to a whole-time position on its scientific staff as director of research in industrial medicine. The investigations to be undertaken by Prof. Ellis and his assistants will in the first instance be directed to problems of industrial toxicology which are of special importance during the War.

FOR the second year, the Rockefeller Foundation has made a grant to enable the Royal Society to assist scientific societies and associations to meet the financial difficulties involved in the publication at the present time of scientific journals. This generosity, which last year benefited a number of bodies, will be widely appreciated.

THE Royal Society of Arts has awarded the annual Thomas Gray Memorial Trust Prize of £50, for an invention advancing the science or practice of navigation, to Mr. T. E. Metcalfe, of Windsor, for the seaman's protective suit devised by him. This suit, which, when not in use, folds into a compact bundle, weighing about 3 lb., forms a complete covering of water- and wind-proof material to be put on when a shipwrecked person reaches a lifeboat or raft. It is being provided by the Ministry of War Transport on a wide scale, and has already saved many men from death by exposure to the elements.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Ascorbic Acid in Oranges

IN 1934 Bacharach, Cook and Smith[1] reported that the concentration of ascorbic acid in the peel of oranges was greater than that in the juice. This was the result of tests carried out on five bitter oranges and one sweet orange, and was afterwards confirmed by various workers[2–6]. In connexion with an investigation on methods of preparing orange juices for drinking purposes we have taken the opportunity of repeating this work. Table 1 gives the results of the examination of eight South African oranges.

TABLE 1.

	Concentration of ascorbic acid		
	mgm./gm.		gm./lb.
	Range	Average	
Whole peel	1·01–2·27	1·52	
Pulp*	0·42–0·64	0·52	
Juice	0·42–0·62	0·51	
Whole orange	0·58–1·09	0·81	0·368

* The pulp consisted largely of the skin enclosing the segments of the fruit together with a little of the inner white skin.

Two methods of preparing orange drinks have been tested: (*a*) using the juice obtained by rotary squeezing and (*b*) using a process in which thin slices of whole orange are extracted by sugar syrup. Referring the ascorbic acid content to a unit weight of one pound of oranges, Table 2 shows the results obtained.

TABLE 2.

	Ascorbic acid	
	gm.	As percent. of whole orange
Whole orange	0·368	—
Juice obtained by method (*a*) Experiment I	0·114	31·0
,, ,, ,, ,, (*a*) ,, II	0·113	30·7
Extract ,, ,, ,, (*b*) ,, I	0·238	64·7
,, ,, ,, ,, (*b*) ,, II	0·238	64·7
,, ,, ,, ,, (*b*) ,, III	0·245	66·6

If therefore it is desired to extract as much ascorbic acid as possible from oranges, method (*b*) is to be preferred, as there is made available by this means about 65 per cent of the total ascorbic acid in the whole orange as against 31 per cent obtained by using the juice alone.

The relative stability of the ascorbic acid in orange juice is generally recognized. It is therefore considered of interest to record one observation of the rapid disappearance of ascorbic acid in minced orange peel exposed to the air.

TABLE 3.

	Concentration in mgm./gm.		
	Ascorbic acid	Dehydro-ascorbic acid	Total ascorbic acid
Initial sample	2·11	0·16	2·27
Sample minced and allowed to stand for 3 hours	0·46	1·43	1·89
Sample minced and allowed to stand for 22 hours	0·14	0·05	0·19

Similar results have been obtained by us with cabbage and are recorded in the literature for cabbage and other vegetables. We are inclined to the view that this disappearance of ascorbic acid may be ascribed to the action of an oxidase.

Effect of Œstrin Injections on the Mouse Ovary

IN 1941 Bullough and Gibbs[1] showed that, both in the mouse (*Mus musculus* L.) and the starling (*Sturnus vulgaris* L.), maximum mitotic activity in the germinal epithelium of the ovary is confined to a short period immediately following ovulation, and it was suggested that, in all probability, some hormone, coming into full operation at this time, stimulates the epithelium to produce large numbers of new oogonia. It has since been shown[2] that a similar post-ovulation peak of mitotic activity is present in the ovary of the minnow (*Phoxinus lœvis* L.), and that in this fish it is possible to stimulate the germinal epithelium to abnormal mitotic activity, and consequently to the production of abnormal numbers of oogonia, by abdominal injections of œstrin.

Similar injection experiments have now been performed on the mouse in an attempt to produce the same effect, and after preliminary work, the following technique was devised. Twelve-hourly injections of œstrin in sesame oil were given abdominally into normal mice in early diœstrus, and the mice were killed 12 hours after the last injection. The germinal epithelium is relatively quiescent during the whole diœstrous period, which lasts on the average about three days[3]. At each injection 250 I.U. of œstrin in 0·25 c.c. of oil were introduced, and the liquid was directed into the vicinity of the ovaries. To facilitate the study of mitoses, 0·1 mgm. of colchicine in 0·25 c.c. of water was injected into each mouse 9½ hours before killing. Unusual mitotic activity of the germinal epithelium was noted after only one injection, but the maximum effect was not produced until after five injections. In the accompanying table the average number of mitoses per ovary (*a*) and the standard deviation from the mean (σ) are given.

The first group, controls receiving no œstrin, showed an average total number of only twenty-five mitoses per ovary. As none of the mice had ovulated, it must be assumed that the large numbers of mitoses obtained in the other groups were due to the effects of the injections. The ovaries of all the injected animals contained far greater numbers of mitoses than the most active of the control animals, but there was very considerable individual variation in all groups. Maximum numbers were found in the germinal epithelium of a mouse which after four injections contained 1,255 mitoses, and in another which after five injections contained 1,818 mitoses.

Average numbers of mitoses of the germinal epithelial cells in control and experimental ovaries.

Number of œstrin injections	Number of mice	Mitoses per ovary *a*	σ
0	12	25	14
1	5	122	67
4	5	664	493
5	4	747	728

It is concluded that, in the normal mouse, the bursting of the Graafian follicles at ovulation releases follicular fluid rich in female sex hormone. This comes into direct contact with the germinal epithelium, causing the observed post-ovulation peak of mitotic activity, and resulting in the replenishment of the ovary with a new stock of oogonia. Recently, other evidence has been brought forward[4] which indicates that œstrin normally causes mitosis and consequent growth in the follicles and corpora lutea, and that it induces the division of cells of the ovarian stroma. It is well known that relatively small quantities of œstrin will cause mitotic activity in the cells of the female accessory sexual organs, but it appears that the ovarian cells require far higher concentrations and are only induced to divide actively when in direct contact with highly concentrated solutions of the female sex hormone in follicular fluid.

Relation of Aeration to the Activity of Proliferation-Promoting Factors from Injured Cells*

IN earlier tests of the proliferation-promoting activity of materials from injured cells ('intercellular wound hormones') in which yeast was used as the test organism[1], the test cultures were grown in rocker tubes with continuous shaking[2]. This subjected them to appreciable aeration. In recent investigations of wound hormones, yeast was again employed as the test organism, but was cultured in stationary, cotton-plugged tubes suspended in a water bath. At intervals of several hours, the tubes were removed from the water bath, shaken, and the yeast population determined with a photo-electric densitometer. In these later experiments, all preparations failed to show appreciable activity, though they had been prepared strictly in accordance with previously used techniques[1].

It was noted that the cultures containing wound hormone preparations frequently exhibited a ring of yeast growth around the inside of the tube at the air-medium interface. This suggested the possibility that the wound hormone preparations are only effective in the presence of oxygen. Furthermore, Fardon, Norris and co-workers[3], in their original investigation of the metabolic effects of products from ultra-violet irradiated yeast, found such preparations to stimulate cell respiration markedly. Hence it appeared possible that the proliferation-promoting action involved the respiratory mechanism of the cells.

To test this point, a roller tube device was constructed in which the cultures, in 3/4-in. test tubes, are attached to a wheel near its periphery and parallel to its axis of rotation. The plane of the wheel is inclined at an angle of approximately 15° from the vertical. This angle is sufficient to prevent wetting of the cotton plugs by the medium in the tubes, while the almost horizontal tube position maintains a large surface of medium exposed to the tube atmosphere. Rotation of the wheel at 54 r.p.m. provides sufficient stirring to prevent sedimentation of the organisms except in extremely dense populations and to aerate the culture to an extent presumably comparable with that obtained in the rocker tube experiments.

Growth Tests of Wound Hormone Preparations
Wet Weight of 24-Hour Yeast Crops, mgm. per ml. of culture
Concentration of materials tested:
0·1 ml. per ml. of culture.

	Stationary tubes	Roller tubes
Product from Injured Cells ...	0·16	4·05
Product from Uninjured Cells ...	0·18	0·70
Control (Reader's medium only)...	0·15	0·09

When wound hormone preparations, inactive in the stationary tube cultures, were tested in the roller tubes, they showed marked activity. A typical example is shown in the accompanying table. The preparation tested in this instance was the cell-free suspension medium obtained from yeast injured by 8-hour irradiation with full ultra-violet radiation in distilled water at a concentration of 100 mgm. wet weight of yeast per ml. Its activity is compared with that of a similar extract from non-irradiated yeast. Considerable cell death (about 6 per cent) necessarily occurred in the non-irradiated suspension due to the prolonged extraction in distilled water; hence this extract, as well as that from the irradiated cells, would be expected to show some wound hormone activity.

The necessity of aeration for growth activity of the wound hormone preparations is apparent from the table. These results have been confirmed by repeated tests in which the progress of growth at various concentration-levels of added materials has been followed at frequent intervals for periods as long as 82 hours. Full details of the experiments will appear elsewhere. Attention should be directed to the greater growth of control cultures in stationary tubes than in roller tubes. This has been observed repeatedly. The explanation is not known.

---

* Contribution No. 199 from the Department of Biology, Massachusetts Institute of Technology, Cambridge, Mass.

The results strongly indicate that the wound hormone activity of products from injured cells is due to the factor or factors involved in the respiratory mechanism of the cells. The similarity of the spectra of wound hormone preparations to those of adenine nucleotide complexes[1], the indicated presence of adenine, pentose and phosphorus, and the absence of pyrimidines[5] would suggest the possibility that the active principle might be diphospho- or triphosphopyridine nucleotide. Against this possibility there are: (1) negative chemical tests for the pyridine ring[4]; (2) negative spectral indications of coenzyme I or II on reduction of the preparations with sodium hyposulphite; (3) negative biological tests for coenzyme I in our preparations. The spectral tests of oxidized and reduced preparations were undertaken in collaboration with Prof. Sizer of our department. The biological assay for coenzyme I was carried out through the kindness of Prof. Ball of the Biochemistry Department of Harvard Medical School by Mr. Jandorf of his laboratory. The possibility of the identity of the active factor with other adenyl nucleotide complexes, such as adenine pyrophosphate, yeast adenylic acid and muscle adenylic acid, is being investigated.

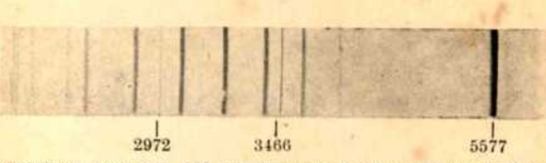
A Remarkable Green Line Source

IN a number of communications in these columns I have reported the observation of high relative intensities of forbidden lines of atomic nitrogen and the forbidden bands of molecular nitrogen in nitrogen afterglows. Both the absolute and relative intensities of these radiations increased with pressure over the range which had been studied up to the spring of 1941. This included pressures from about 0·001 to 30 mm. In addition, the relative intensities increased as the time between the interruption of the afterglow producing discharge and the exposure of the afterglow was increased[1]. This effect has been referred to as the temporal effect.

One of the tubes that had been used during the previous studies was cleaned and refilled with nitrogen at the high pressure of 100 mm.[2]. This tube developed a strong afterglow in a remarkedly short time, and in a few days it showed an afterglow so rich in the green auroral line that after the first half-second the afterglow was coloured green and the green line could be seen for several seconds in a vision spectroscope. The spectrum which was chosen for reproduction here shows that after the first flash of the afterglow during which the first-positive and second-positive bands of N_2 are considerably weakened, we have an almost monochromatic source of the green auroral line in the visible. The large intensity of OI $'S_0\text{-}3P$, which has about one thirtieth the transition probability of the green line OI $'S_0\text{-}'D_2$, shows in a striking manner the remarkably efficient excitation of the green line. In addition, one should note the large intensity of NI $2P\text{-}4S$.



AFTERGLOW SPECTRUM 100 MM. PRESSURE NITROGEN WITH TRACE OF OXYGEN; FIRST HALF-SECOND OF AFTERGLOW NOT PHOTOGRAPHED.

Since the discovery of this source, another similar tube at 50 mm. has been prepared, and this, too, shows equally strong forbidden oxygen and nitrogen line excitations. Therefore, the effect must be due to some change in the tube other than pressure. Other features of the afterglow show up as the small amount of oxygen disappears. Among these is the unexpectedly large intensity of the first-negative (auroral) bands of N_2^+ at both 50 mm. and 100 mm.; the large intensity of the Vegard-Kaplan bands and the large intensity of the green line when much of the oxygen has cleaned up.

These results and a proposed hypothesis to account for these tubes will be presented later, but one conclusion is already tempting, namely, that the catalytic effect of the walls of the tube for the destruction of active nitrogen has in some way been removed and the tube behaves effectively as if it had *no walls*. The large intensities of the two most striking components of the auroral spectrum, the green line and the auroral bands, lend considerable weight to this conclusion, because both ions and metastable atoms are effectively quenched at walls.

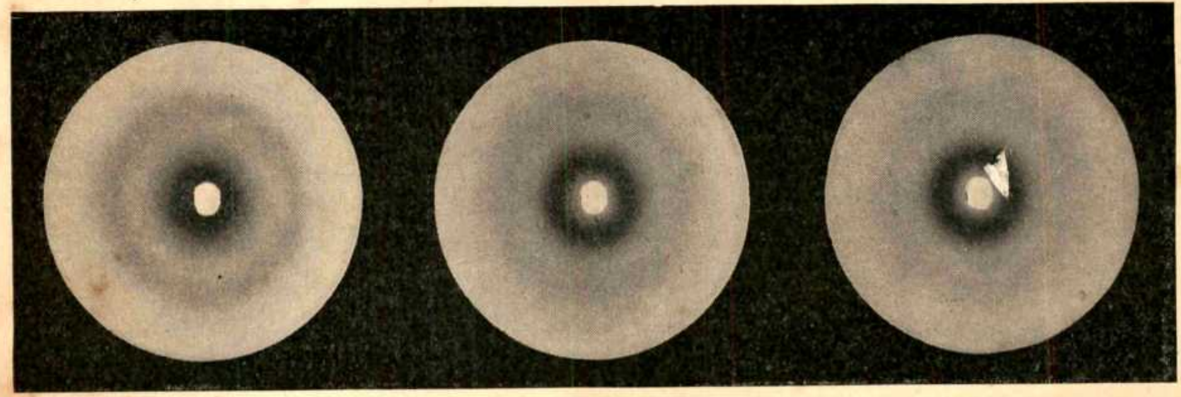
Structure of Vitreous Silica

OUR attention has recently been directed to a letter from S. S. Lu and Y. L. Chang[1] concerning the structure of vitreous silica. Two main claims are made. First, that the X-ray diffraction pattern of a thin plate of vitreous silica differs from that of the powdered material and consequently there must be some rearrangement of structure on powdering. Secondly, that the relative intensities of two strong bands in the pinhole transmission photographs of the thin plate vary according to the location of the specimen and that this indicates that large fluctuations occur in the structure of vitreous silica. Since, if true, these results would appear to suggest that the random network theory developed by Warren[2] is based upon incomplete experimental data, the experiments and conclusions described in the letter are worth critical examination.

It may be pointed out that Warren's investigation was carried out with considerable care, and precautions were taken to eliminate spurious effects. For example, the X-rays were monochromatized by crystal reflexion ; also background and small-angle scattering were reduced to a minimum by evacuating the camera. There is no precise description in Lu and Chang's letter of the experimental arrangements for taking the X-ray patterns, but it does not seem that crystal-reflected X-rays were used. It must be assumed, therefore, that the more usual method of filtration was utilized to obtain the copper $K\alpha$ radiation and that there would consequently be a white radiation component of the X-ray beam. The presence of this would provide a simple explanation of the particular form of the pinhole transmission photographs obtained by Lu and Chang. Broadly speaking, they obtained two strong bands in the transmission photographs of a thin plate of vitreous silica, thickness 0·5 mm. These bands could be derived from the same fundamental spacing in the glass structure, the outer band at 4·09 A. from diffraction of the characteristic $K\alpha$ radiation and the inner band at 8·18 A. from diffraction of the white radiation. A thickness of 0·5 mm. is too great for use with copper $K\alpha$ radiation, which would be substantially absorbed ; there would be differential absorption of the X-ray beam actually employed, the shortest wave-length part of the white radiation being much more readily transmitted than the longer wave-length characteristic radiation.



0·05 mm. 0·43 mm. 0·50 mm.

In order to test this we have obtained pinhole transmission photographs over the thickness range 0·5–0·05 mm., using filtered copper $K\alpha$ radiation. These show that the relative intensity of the inner band decreases continuously with the specimen thickness, the band effectively disappearing below about 0·1 mm. Three of these photographs corresponding to thicknesses of 0·05, 0·43 and 0·50 mm. are reproduced here. The blackening near the centre of the pattern of the 0·05 mm. specimen arises from small-angle scattering by air of long wave-length components (largely no doubt the copper $K\alpha$ wave-length) of the X-ray beam. Such blackening is much reduced on the other patterns because of substantial absorption of these wave-lengths by the thicker specimens.

By varying the tube voltage we have also confirmed that the position of the band changes with the wave-length distribution of the white radiation. These results provide strong evidence that in Lu and Chang's photographs the inner band is spurious and probably arises in the way we suggest. It is obvious that changes in the intensity of this band cannot be significant of structural variation between contiguous regions. Such intensity fluctuations might result from small changes in the experimental conditions and from any variation in thickness.

The faint but comparatively sharp lines at 3·35, 2·48 and 1·88 A. appearing in some of Lu and Chang's powder photographs correspond closely in position to three of the strongest lines in the X-ray pattern of crystalline quartz. These are just the lines which would be most likely to occur as the result of contamination of the powder with material from an agate mortar during grinding. In regard to the band at 5·80 A., it would be interesting to know what kind of medium was used for holding the powder together in the form of a cylindrical rod. Canada balsam, for example, gives a band in this position. Using the minimum quantity of cellulose binder, we have obtained a pinhole transmission photograph of a slab of powder which shows no evidence of a band in the region of 5·80 A. The photograph of the powdered material is, in fact, very similar to that of a 0·25 mm. plate.

It is therefore reasonable to conclude from these results that the bands at 8·18 and 5·80 A. obtained by Lu and Chang are spurious, and the changes they report should not, therefore, be taken as evidence of variation of structure either between neighbouring regions of a slab of vitreous silica or on powdering. Furthermore, there would seem to be no reason to suppose that the random network theory of Warren does not cover the facts.

RESEARCH ITEMS

Incomes in Rhodesia

IN a paper reprinted from the *Transactions of the Rhodesia Scientific Association* (38, 63–73; April, 1941) J. R. H. Shaul has used the published returns of the Commissioner of Taxes in his annual report for the year ended March 31, 1938, which covers the year 1936–37, and the results of the census of population, 1936, to examine the distribution of incomes originating in Southern Rhodesia in 1936. Within certain limits, these incomes can be accurately described by Pareto's law. Formulæ are given for all incomes, for married persons and for other persons, and the available evidence suggests that the formula for all incomes changes its gradient at £350 and can therefore be utilized only in respect of incomes exceeding £350. Below £350 the following hypothetical expression for Pareto's law is deduced:

$$\log y = 5{\cdot}457 - 0{\cdot}515 \log x \; (2{\cdot}053 < \log x < 2{\cdot}544).$$

The hypothetical formula for the distribution of income in Southern Rhodesia is:

$$\log y = 9{\cdot}558 - 2{\cdot}127 \log x \; (\log x < 2{\cdot}544)$$
$$\log y = 5{\cdot}457 - 0{\cdot}515 \log x \; (2{\cdot}035 < \log x < 2{\cdot}544).$$

Petrology and Prehistory

AN important article on this subject appears in the *Proceedings of the Prehistoric Society* for 1941 under the signatures of A. Keiller, Stuart Piggott and F. S. Wallis. A large number of stones celts have been studied microscopically, a tiny portion of each tool being sliced and the outer surface of it replaced in such a way that finally it is almost impossible to detect that anything has been done to the specimen —compare the technique of the cheese-taster! The composition of the rock having been determined, it is often possible to say with fair accuracy whence came the raw material from which the tools were made. Naturally this information can help in elucidating prehistoric trade routes, or at any rate can throw light on the movements and contacts of peoples. For example, it is apparent "that while the most important area supplying the raw material for the stone axes of Wessex was Cornwall, axe-factories in North Wales and Cumberland exported their products as far south as Wiltshire at least". Such investigations, when continued further, will certainly yield very fruitful and often exciting results.

Inhibition of Growth by Chemical Compounds

MANY carcinogenic hydrocarbons retard the growth of both normal and malignant tissues and an association exists between the biological properties of carcinogenicity and growth inhibitory power. Tumour induction is conceived to take place in two stages: (1) interference with the growth of normal cells and (2) an adaptive cellular reaction, accomplished mainly by dedifferentiation, where the altered cells are able to achieve independent multiplication at an increased rate in an environment which makes normal growth difficult or impossible for their parent cell. While the new growth characters appear in response to a specific pathological change in the cellular milieu, the cellular changes themselves are permanent and continue to be manifested indefinitely and without reversion when the variant cells reach normal tissues either in the same host or artificially in other hosts by transplantation. With the prospect of discovering compounds possessing enhanced inhibitory activity, but with carcinogenicity restricted, G. M. Badger *et al.* (*Proc. Roy. Soc.*, B, 130, 255; 1942) have investigated the growth inhibitory activity of more than two hundred carcinogenic compounds and related substances. A striking degree of correspondence was often shown by the inhibitory and carcinogenic activity of closely related compounds, such as dibenzfluorenes or dibenzphenanthrenes, although no inhibitory activity was observed for certain carcinogenic 10- and 9 : 10 substituted benzanthracenes. Conversely, inhibitory activity was noted in a few compounds (1 : 2′-azonaphthalene) which have yielded few or no tumours in exhaustive tests, and in some of a group of synthetic œstrogens, which although not carcinogenic in the usual sense are nevertheless associated with the induction of individual types of tumour under special conditions. The results obtained with derivatives of triphenylethylene suggest that inhibitory activity may still be shown by compounds diverging widely from the polycyclic structure and possessing only a skeletal resemblance. In view of the similar inhibitory effects produced on body growth, tumour growth and gonadal activity by the polycyclic carcinogenic hydrocarbons and by œstrogens, carcinogenic in a restricted sense, it is likely that the mechanism in both cases is partly direct and partly moderated by the pituitary.

Streptolysin O

MANY strains of hæmolytic streptococci produce filterable hæmolysins. The hæmolytic activity of fresh broth filtrates in which hæmolytic streptococci have grown rapidly disappears on standing in air and can then be restored to the original level or higher by the addition of reducing agents such as hydrosulphite. This hæmolysin (streptolysin *O*) is produced by most strains of group *A* streptococci when grown in serum-free broth, by group *C* strains from human infections and by group *G* strains, but not by streptococci of other groups. Another serologically different hæmolysin (streptolysin *S*) is produced when hæmolytic streptococci are grown in media containing serum, and its activity is not affected by oxidation and reduction. Herbert and Todd (*Biochem. J.*, 35, 1124; 1941) have purified streptolysin *O* and have shown it to be a protein which hæmolyses red blood corpuscles only after activation with reducing agents such as compounds with -SH groups, resembling certain other enzymes, for example, papain, in this respect. A possible explanation of the hæmolytic action of streptolysin *O* is that it is an enzyme which attacks a constituent of the red cell membrane. Although no appropriate substrate has yet been found for the demonstration of its enzymic function, yet the extremely small doses in which all bacterial toxins work suggest that their action must be catalytic. It is noted that two bacterial toxins have already been identified as enzymes, namely, the α-toxin of *Cl. welchii* as a lecithinase, and the 'diffusing factor' of the same organism and of streptococci as a hyaluronidase, and the possibility exists that all bacterial toxins are enzymes.

New Silver Firs from Asia

THE activities of various botanical explorers in eastern Asia have made an immediate contribution to floral beauty in the garden, but the taxonomic and horticultural evaluation of trees is a slower process. Nurseries at Chandlers Ford and Winchester have been used to propagate the newer Asiatic silver firs from seeds collected by Forrest, Wilson, Kingdon Ward and others. Edwin L. Hillier has now described some of the species there which have grown sufficiently to provide reliable specific characters (*J. Roy. Hort. Soc.*, 66, Pts. 11 and 12, Nov. and Dec., 1941). The Chinese silver fir, *Abies Georgii*, and *A. Forrestii* promise well as ornamental trees, and sixteen other species are described in detail, mainly from the horticultural point of view. It is still too early to assess any significance the various species may have for afforestation in Great Britain, but the English material should provide useful data for a future ecological comparison with trees in the native habitat, for most of the original collections are from sites above 10,000 ft. high.

Linkage Studies

F. B. HUTT (*J. Hered.*, 32, 357; 1941) for the fowl, and W. E. Castle and P. B. Sawin (*Proc. Nat. Acad. Sci.*, 27, 519; 1941) for the rabbit, report the discovery of a fifth linkage group. Multiple-spurs are linked with duplex comb in the fowl with a cross-over percentage of 28 per cent. Multiple-spurs which are characteristic of the black Sumatra fowl are inherited as a dominant and may be easily detected in 98 per cent of young chicks. In the rabbit, furless and brachydactyly are linked with a cross-over of 28 per cent, while dwarf is now added to the agouti-wide-band linkage group.

Solar Radiation and Atmospheric Temperature

DR. H. ARCTOWSKI, a well-known Polish meteorologist who was stranded in the United States by the outbreak of war, has been investigating the effect of variations of solar radiation on atmospheric temperature, and his first results have been published (*Smithsonian Mis. Coll.*, 101, No. 5). He found that while in a few cases a direct effect on surface temperatures could be shown, these are exceptions, and he concluded that while solar variations are undoubtedly important, their effects are very complex, and probably occur mainly in the upper air. The greater part of the paper therefore consists of a study of the variations of temperature up to 17 km., mainly on the basis of *radio-sonde* ascents in the United States. Waves of rising or falling temperature, with their accompanying effects on pressure, travel in different directions at different heights, so that the combined effect at the surface is one of almost inextricable confusion, but there is a possibility that a direct effect of solar variation on temperature may occur at some level in the stratosphere. Dr. Arctowski however distinguishes *two* tropopauses, polar and equatorial, which are superposed in temperate latitudes. Very little attempt is made to relate the observed changes of temperature at any height directly to observed variations of the solar constant, and it is evident that many more data are required before there is any hope of a solution of this important problem.

Adsorption of Metals of the Iron Group in Analysis

A PAPER on the above subject was read by G. J. Austin before the Society of Public Analysts and Other Analytical Chemists on February 4. The effect of *p*H on the adsorption and solubility of aluminium hydroxide in analysis has been studied. The ammonia method of separating aluminium from nickel was shown to be impracticable owing to the great increase in the adsorption of nickel over a limited range of *p*H. Data were given comparing the extents to which adsorption takes place in the precipitation of iron, aluminium and chromium by the ammonia method, the benzoate method and the author's phosphate method. Some other methods were also referred to. It was shown that the phosphate method is better than the ammonia method in minimizing adsorption, but that in absence of phosphate the benzoate method is better than the phosphate method.

Solvent Effect and Dipole Moments

IT has been known for some time that the dipole moment of a compound measured in solution may differ from that measured in the vapour state. The reason for this difference is broadly known and the so-called solvent effect has been studied in many cases. In the measurements, both with vapour and liquid systems, the main difficulty is now the estimation of the so-called atom polarization, which cannot be determined directly. By combining the two sets of measurements, some of the uncertainty attached to atom polarization may be removed. A. Audsley and F. R. Goss (*J. Chem. Soc.*, 864; 1941) have now discussed methods for distributing the polarization of binary liquid mixtures between their components. The so-called distortion polarization, the sum of the electronic and atom polarizations, $P_E + P_A$, obtained by the elimination method just mentioned, has been distributed over the carbon, hydrogen and halogen atoms in compounds of the type RX by making use of an additive relation in which $P_E + P_A$ is the sum of contributions assigned to each atom or bond. It is shown that on ascending the series from fluorine to iodine the electron polarization P_E increases but the atom polarization P_A shows a general tendency to decrease.

High-voltage Porcelain Insulators

A PAPER read recently by J. S. Forrest before the Institution of Electrical Engineers discusses the electrical characteristics and performance in service of porcelain insulators for outdoor apparatus for voltages between 33 and 220 kv., and emphasizes the necessity for a carefully planned field-testing scheme supplemented by laboratory investigation if system breakdowns are to be minimized. The first part describes the laboratory and field-testing equipment used by the Central Electricity Board and proceeds to an outline of the technique employed. The second part gives details of investigations made with the apparatus and methods previously described, and information is provided regarding the performance of line insulators, post insulators and bushings, discussing their behaviour under adverse weather conditions. Comparative results are given for normal and anti-fog insulators, the mechanism of insulator flashover in fog being described in detail with suggestions for a good anti-fog insulator. A discussion on the deterioration of insulators in service advocates field-testing to prevent single faulty units of suspension insulators leading to a complete breakdown of the string containing them, and describes the mechanism of insulator failure due to cracking. Considerable attention is given to the cause and characteristics of radio interference due to power lines, data being given of the interfering field strength under various weather conditions.

THE SUN AND THE IONOSPHERE

THE thirty-second Kelvin Lecture of the Institution of Electrical Engineers was delivered by Prof. Sydney Chapman on May 8, 1941, and has now been published (*J. Inst. Elect. Eng.*, 88, Pt. 1, No. 11, Nov., 1941). The first part of Prof. Chapman's lecture, dealing with the origin of solar energy by the 'combustion' of hydrogen, was printed in NATURE of June 28, 1941, p. 792.

The process begins when the solar gas has reached a temperature of 20×10^6 °C. and a pressure of 10×10^9 atmospheres near the sun's centre, the 'burning' of the hydrogen nuclei thereafter maintaining the temperature and preventing further contraction for thousands of millions of years. In this reaction, the hydrogen protons are built up into helium nuclei during a six-stage reaction involving a catalyst, which at the outset is an ordinary carbon nucleus $^{12}_{6}C$. The equations of these reactions indicate a few million years for the fertilization of a carbon nucleus by four successive protons to beget one α-particle. If the birth-rate is high at the sun's centre, it is on account of the immense number of carbon atoms and protons.

This catalytic reaction is enormously productive of energy, 1 lb. of hydrogen nuclei evolving radiant energy equivalent to 100 million electrical units, compared to 4½ units for 1 lb. of coal. Energy has a mass of 1 gm. per 25 million electrical units, and hence the radiant energy from 1 lb. of hydrogen nuclei has a mass of 4 gm., by which perceptible diminution the mass of the resulting helium nuclei falls short of 1 lb. For a loss in mass of four million tons/sec. the sun has a heating and lighting output of 10^{24} kw. Radiation leaves the sun with a spectral distribution corresponding roughly to 6,000° C., consisting of highly directional electromagnetic waves, the average frequency of which is nearly a billion kc./sec. In the sun's upper layers the outward flowing radiation energizes many surface phenomena, the most evident being sunspots and prominences. Much solar gas in prominence form leaves the sun, which thus sends forth matter as well as radiation into surrounding space; and this matter, in the form of rare gas streams, assists the solar radiation in the ionization of the earth's outer atmosphere.

All but a tiny fraction of the sun's colossal energy output is lost in space, the earth's input of 170 billion kw. being but one thousand millionth of the parental output. Prior to entry into our atmosphere, this includes radiation of all wave-lengths, which may be resolved into a spectrum containing visible radiation or sunlight proper, ranging from violet to red (3900–7700 A.), and outside this the infra-red and ultra-violet. Much of the sun's light and heat pass through the atmosphere to the earth's surface, but the blue sunlight is dispersed. At an altitude of 15 miles above the atmosphere the sky is dark as at night. Energy absorbed by land and sea energizes almost all living processes, weather phenomena and geological changes, afterwards returning to space as heat radiation. Very little of the sun's radiation reaches the ground, the rest being absorbed at different levels by ozone, oxygen and nitrogen. Between 10 and 70 miles altitude, dissociated oxygen atoms combine with oxygen molecules to form ozone, an extremely rare constituent of the atmosphere, which, if collected at the earth's surface would, at the prevailing temperature, have a thickness less than $\frac{1}{8}$ in. This very small amount, spread through 30–40 miles of atmosphere, absorbs all the ultra-violet radiation (from about 2000 A. to 3000 A.), and also some of the visible and heat radiation—in all, about 5 per cent of the whole incident energy. At an altitude of 7 miles, the temperature is 220° abs. (−53° C.), rising with increasing altitude to greater than 100° C., cooling again after a further 25 miles, according to the band spectrum evidence of the Northern Lights.

The absorption of radiation in the extreme ultra-violet end of the spectrum can ionize molecular oxygen and nitrogen, which, absorbing at different levels, can provide a two-layer ionosphere. Appleton recognized the existence of two distinct main ionized layers: the lower or E layer, at 60 miles, and the upper or F layer. The latter in day-time in middle and lower latitudes consists of two parts, F_1 at 130 miles and F_2 at 200 miles. The E layer appears to remain nearly constant in height, whereas the F_2 varies greatly. Absorption of the ionizing solar radiation is more likely to be due to molecules than to atoms. Molecular nitrogen extends upwards for hundreds of miles above the ground, whereas molecular oxygen is probably scarce at 70–80 miles; hence the ionized nitrogen layer is likely to be situated above the ionized oxygen layer and we may probably identify the nitrogen layer with F, and the oxygen layer with E. Appleton and Hulbert consider that the temperature of the F_2 layer rises, due to some radiant energy being absorbed and converted into heat within the layer, causing an upward expansion and rarefaction of the layer and demanding remarkably high temperatures of the order of 1,000° abs. Such temperatures imply large random molecular velocities in the F_2 layer, weakening the earth's gravitational attraction on the air there, especially for hydrogen and helium, which probably leak away into space. Helium has constantly been reproduced radioactively from the earth's crust for more than a thousand million years, but the atmosphere does not contain the corresponding amount of helium. When the layer cools in the late afternoon it sinks, producing the abnormal second maximum of ionization.

Solar control of the ionosphere is indicated by the change in electron density following the 11-year sunspot cycle, the ionization having changed by 50–60 per cent between the sunspot minimum of 1934 and the sunspot maximum of 1937, implying a still greater increase, of 120–150 per cent, in the ultra-violet intensity. A similar change has long been revealed in the intensity of the system of electron currents flowing in the upper atmosphere, by their daily magnetic field variation, and this gave the first indication of an ionosphere, long before the advent of radio communication. The most remarkable irregular ionospheric changes are those associated with magnetic storms, causing long radio black-outs of hours or days and slowly rectifying abnormalities in the earth's magnetic field. The F_2 layer is most usually affected, except in high latitudes, where the E region may be intensified and extended downwards to cause a radio black-out resembling those due to solar eruption, except that they may occur at night and be of longer duration. Appleton and his collaborators have discovered that the earth's field imposes a spiral character on the motion of electrons in the ionosphere, making the air anisotropic for the transmission of radio waves, permitting determination of the field intensity in the region of refraction of returned waves; and that the E layer sustains lunar tidal motion twice per lunar day, the ionospheric tide having the unexpected range of about 1 mile, and producing by dynamo action a system of electric currents, detectable by their magnetic effects at the ground, apparently flowing in or below the E layer.

There also flows in the ionosphere a system of currents wholly governed by the sun, manifesting themselves by ordinary daily magnetic variations, the total current being about 200,000 amp., roughly ten times as great as those due to lunar tides. The total current intensity in the greater system is only about twice that of a single lightning flash and the current density is extremely low, contributing inappreciably to the heating of the atmosphere. In a quite moderate storm there appears to be an intense current system (more than half a million amperes) in the ionosphere over each polar cap; the magnetic effects over the remaining ·90 per cent of the earth betoken a current system of about the same total intensity.

ELECTRONICS IN INDUSTRY

IN May 1941, as a result of considerable interest in the various branches of industrial radiology, the Institute of Physics formed an Industrial Radiology Group (see NATURE, June 7, 1941, p. 706). Recently there has been a widely expressed wish among members of the Institute for the formation of a similar group for electronics. It was decided, therefore, to hold a Conference on Electronics to ascertain whether there existed sufficient interest to justify the formation of such a group. This Conference was held at the Royal Institution on January 28 under the presidency of Prof. J. D. Cockcroft. It consisted in the reading of three papers followed by a general discussion and was well attended, members from many parts of Great Britain being present, as is usual at such meetings of the Institute.

Prof. Cockcroft, opening the proceedings, spoke of the widening field of application of electronic devices, and said that it is becoming increasingly difficult for physicists to keep in touch with developments in such specialist fields. He thought that the Conference would justify itself if it helped to minimize this difficulty.

The first paper, on "The Efficient Production of Light by the Electric Discharge", was read by V. J. Francis of the General Electric Company. The author pointed out that the scientific study of the efficient conversion of energy into radiation by means of electric discharges in gases is comparatively recent. Although the efficiency obtainable is several times that possible by any other known means, in practical lamps the efficiency of conversion is still only 12–15 per cent, and a wide field for research still exists. Under certain ideal experimental conditions, efficiencies as great as 90 per cent have been recorded.

Mr. Francis then discussed the sodium and mercury vapour discharges in order to explain some of the principles involved in obtaining high luminous efficiency. The former requires low pressure and low current density because the resonance radiation is in a useful part of the visible spectrum; while with mercury, where the useful transitions are between excited states, the conditions leading to high efficiency are high pressure and high current density. He then dealt briefly with some of the applications of luminescent powders to discharge lamps. In one interesting application, practically all the light is obtained from the luminescent powder, which is excited by ultraviolet radiation produced with an efficiency of some 70 per cent in the low-pressure mercury vapour discharge. Finally, the possibilities of the mercury vapour discharge as a high-brightness source were mentioned; very high brightnesses are possible by this means.

The next paper, on "The Control Characteristics of Thyratrons and Ignitrons", was given by H. de B. Knight, of the British Thomson-Houston Company. The author first dealt with the dependence of the ratings and control characteristics of hot-cathode thyratrons on cathode emission, on the geometry of the electrodes and envelope, and on the gas or vapour density. In gas-filled valves the density is constant and control characteristics are independent of temperature; but the working voltage is limited to about 500 volts. For high power, mercury vapour is used; but the vapour pressure must be controlled, especially for heavy current densities and high voltages (above 15 kv.) Mr. Knight showed many interesting curves illustrating these characteristics. Ionization time comprises a delay period in which practically no current passes, followed by a shorter 'build-up' period in which the plasma becomes established. Both periods are relatively independent of vapour pressure, but are affected by the grid voltage and resistance, and especially by the shapes of the electrodes and the field distribution in the arc space. De-ionization time is a function not only of valve design but also of the circuit.

In dealing with mercury pool rectifiers, controlled by cathode spot formation, the author said that the 'Ignitron' alone finds wide industrial application. The delay time between the igniter current and the main arc depends on the rate of rise of igniter current. A delay of less than one microsecond can be obtained; but up to 50 microseconds or more is satisfactory for most industrial uses.

A. J. Maddock, of Standard Telephones and Cables, read the third paper, on "Hot-cathode Gas-filled Triodes (Thyratrons) and their Applications in Research and Industry". The author described the various ways in which these devices may be used. An outline of the principles of the several basic circuits that can be employed in most applications was given, and these were illustrated by interesting demonstrations so that the properties of the various circuits and the effects resulting from the use thereof were readily apparent.

The circuits discussed included those for use on A.C. and D.C. supplies, and showed the range of control obtainable in the former case as the point at which the grid loses control in each positive half-cycle of the alternating anode voltage is varied; and in the latter case how a second thyratron or switch may be used to stop the flow of current through a thyratron already passing current by applying a negative impulse to the anode of the first thyratron. Extension of this leads to the inverter circuit which produces an A.C. output from a D.C. input.

Several grid circuits were illustrated suitable for use in covering such applications and control as timing, impulse, variable reactance, variable resistance (including use of photo-electric cells), variable phase, etc. Examples of the use of these devices ranged from circuits for high-speed counting of physical phenomena and the generation of current pulses of accurate time duration used in research to large industrial plants such as high-tension rectifiers developing 600 kw. at 14,500 volts, large variable-speed motors operating on an A.C. supply, and inverters with the possibility of transmission at high D.C. voltages, together with the realization of a virtual static D.C. 'transformer'.

A lively discussion ensued which ranged over a number of topics, and in particular many questions were asked concerning the behaviour and application of the gas-filled triodes. It was clear, as Prof. Cockcroft said in closing the discussion, that there was sufficient interest for the Conference to go on indefinitely, and the Conference passed a resolution requesting the Board of the Institute of Physics to sanction the formation of an Electronics Group.

UTILIZATION OF INDIAN HOME-GROWN TIMBERS

A FOREST Bulletin, No. 92, Utilization (New Series), has been written by V. D. Limaya of the Forest Research Institute, Dehra Dun, on "The Testing of Packing Cases for Army Boots and suggested Improvements." (Govt. of India Press, New Delhi, 1941). Packing cases for army boots in India have usually been made of chir (*Pinus longifolia*) in the past. Owing to the large demand brought about by the War, other timbers for the purpose have come under review. The Ordnance Department suggested that semul (*Bombax malabaricum*) might answer equally well and would be more easily available as the species is not more or less confined to the outer hills of the Himalayan range. Since, however, it is a softish wood, doubts were expressed as to its suitability. Comparative tests of both timbers were therefore undertaken in the Timber Testing Section of the Institute. These tests showed that semul boxes were practically as strong as chir boxes and possessed in addition certain advantages. But the tests went further, and indicate how war-time emergencies sharpen the faculties. It was discovered that the original design could be greatly improved so as to produce a far stronger box by very small additions costing not more than two annas a box. Boxes so made were tested and found to be fifteen times stronger than those made according to the original design. The advantages to an army at war will be readily understandable. Two plates show the old box and its failure to stand certain stresses and the new one.

Bulletin No. 93, by the same author, is entitled "Indian Timbers for Tool Helves and Handles". When there has been a Forest Department in India for nearly eighty years and a Research Institute for well over thirty, it is difficult to account for the fact that up to quite recently very large quantities of hickory and ash handles were imported from America into India annually. In fact the big American manufacturers were doubtless correct in saying that "We 'handle' the World". Hickory only grows in the lower Mississippi valley and yet hickory tool handles and helves are to be found in use in practically every country in the world. Ash is also used to a very large extent for the lighter types of handles. These two species have very nearly monopolized the tool handle trade of the world. Until comparatively recently this remained true for India in spite of the large number of species growing in the great Indian forests.

The work carried out at the Forest Research Institute has, however, resulted in greater interest being taken in Indian timbers in this respect, with the result that more than three quarters of the railway demand for tool handles (the largest demand in the country) is now met by handles made in India from Indian woods.

The author states that "wooden handles for tools are really becoming a world problem". Manufacturing processes require the use of various types of cutting tools and hammers and the demand for wooden handles for such tools has increased enormously. While admitting that hickory is rather a special type of timber and that it will probably remain in demand for special uses, it is now proved that certain Indian timbers fulfil the requirements for tool handles. The research work of the Timber Testing Department had resulted in the markets being supplied with tool handles made from Indian timbers, and the War has given a great impetus to the tool handle trade, large orders having been placed for pick-axe helves, hammer handles, axe-helves, wooden mallets, handles for entrenching tools, spades and so forth.

Some of the species of timbers used belong to about twenty genera. These, according to their qualities, are used for heavy hammer handles (hickory class), light hammer handles (ash class), axe helves (hickory class), handles for scooping tools (ash class) and handles for cutting tools (beech class). Other woods of small forest species are being tested. For example, *Anogeissus pendula*, which until recently was practically unknown as a tool handle wood, has been found to be the toughest timber ever tested.

DOWNWARD RADIATION OF THE EARTH'S ATMOSPHERE

IN Scientific Notes of the India Meteorological Department (8, No. 93) R. Narayanaswami gives a comparison between measurements of the downward radiation of the earth's atmosphere at night made by himself at Bombay between March 1937 and October 1938 and similar observations by Ramanathan and Desai at Poona in 1930–31. The interest of the comparison lies in the fact that the climates of the two places are in strong contrast, Bombay having a coastal climate of exceptional dampness, while at Poona the climate is continental apart from the rainy season (June–September), and at times very dry, the annual rainfalls being about 70 in. and 27 in. respectively.

The instrument used both at Bombay and at Poona for measuring the atmospheric radiation was Angstrom's pyrgeometer No. 48, made by G. Rose of Upsala. With this was measured the net radiation per horizontal square centimetre, that is, the difference between the full emitted black body radiation given by σT^4 and the radiation received from the atmosphere, interest attaching mainly to the comparison between the ratio sky radiation to full radiation, and the vapour pressure of the air around the instrument calculated from the readings of an Assmann psychrometer. Since the radiation from the sky is practically all due to the water vapour in the atmosphere, dry air being an exceedingly bad radiator, in so far as there is considerable positive correlation between the water vapour pressure near the ground and in the overlying atmosphere as a whole, so the ratio $S/\sigma T^4$, where S is the sky radiation, and the vapour pressure near the ground, show high positive correlation. Comparison between these quantities and the dry-bulb reading of the Assmann psychrometer is made by tables and graphs.

Throughout the year, except possibly in October, the excess of S at Bombay compared with Poona is almost as marked as is the excess there of vapour pressure. An interesting point confirming that it is mainly the annual variation of vapour pressure that causes the annual variation of S and not the annual variation of temperature is to be noted at the onset of the monsoon in June. Temperature falls but vapour pressure and cloudiness increase in the monsoon current, with the result that S continues high. The lowest observed value of S at Bombay was 0·41 gm.cal./cm.^{2} and the highest 0·66 gm.cal./cm.^{2}. At both places the maximum for S is in the monsoon and the minimum in the winter.

FORECASTING MONSOON RAINFALL

IN Scientific Notes of the India Meteorological Department (8, No. 95) V. Doraiswamy Iyer and C. Seshachar have usefully extended some work done by Sir Gilbert Walker in 1921 on the forecasting of the monsoon rainfall of Mysore State as a whole from the three factors: mean atmospheric pressure over India in the preceding May, Zanzibar rainfall in the same month, and Java rainfall for the period October–February. The multiple correlation coefficient obtained in this way was + 0·57.

It is shown by means of a map of normal monsoon rainfall (June–September) that Mysore includes two regions of widely different rainfall, the *Malnad*, which is a narrow strip of country adjoining the Western Ghats, with a monsoon fall varying from 30 in. to more than 300 in., and the *Maidan*, or plain country, which lies farther to the east and includes most of the State, with a fall of less than 30 in. Monthly normals show that in the *Malnad* July is much the wettest month, followed by June and August, whereas the rainfall of the *Maidan* is greatest from May to October with a much less pronounced maximum spread over September and October. It is known, further, that a strong monsoon circulation favours the rainfall of the *Malnad*, whereas a weak monsoon is more productive of the heavy convectional showers that give the *Maidan* a large part of its rainfall. The expectation that higher correlation coefficients might be expected for each of these regions considered by itself, when the factors used are those most suitable to each rainfall regime, than the one found by Walker for the whole State was fulfilled.

Using a number of new factors, which included sunspot numbers, multiple correlation coefficients of 0·60 and 0·70 were found for the *Malnad* and *Maidan* regions respectively. The work was extended in the case of the *Maidan* to the period September–November so as to include the two wettest months for that region, and for forecasting the rainfall of this period a multiple correlation coefficient of 0·75 was found. The factors used in this case were the *Malnad* rainfall for the previous June–August, Bangalore mean winds at 2–3 km. height in July and August and mean India pressure gradient in July and August. The effectiveness of each of the three formulæ is roughly illustrated by graphs of calculated and observed rainfall over a long period of years. These suggest that the forecasts would be of value to engineers concerned with water supply and to agriculturists, in spite of occasional failures due to the fact that the basic correlation coefficients fell very far short of unity.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public)

Saturday, March 7

Geologists' Association (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Mr. W. P. D. Stebbing: "A Review of References to Geology and Allied Subjects from the 16th Century" (Presidential Address).

Monday, March 9

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5 p.m.—Capt. D. L. Leach: "The Survey of Sarawak".

Tuesday, March 10

Chemical Engineering Group (Society of Chemical Industry) (joint meeting with the Institution of Chemical Engineers) (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Mr. N. Fleming: "Noise and its Suppression".

Illuminating Engineering Society (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Discussion on "Advance Planning in Lighting Reconstruction", to be opened by Mr. Howard Robertson.

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir Lawrence Bragg, F.R.S.: "Metals", 2: "Metal Geography".*

Friday, March 13

Royal Society of Arts (India and Burma Section) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Colonel Sir Arthur Olver: "Animal Husbandry in India".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (woman) in Mathematics—The Secretary, Somerville College, Oxford (March 10).

Educational Psychologist—The Secretary for Education, Education Offices, York (March 12).

Deputy Borough Electrical Engineer—The Town Clerk, Town Hall, Sunderland (endorsed 'Appointment of Deputy Borough Electrical Engineer') (March 14).

Engineering Assistant—The Chairman, Mid-Kent Water Company, Snodland, Kent (March 15).

Organizer of Agricultural Education for the Administrative County of Kesteven—The Clerk to the County Council, County Offices, Sleaford, Lincs. (March 16).

Lecturer in Anatomy—The Secretary and Registrar, University, Bristol (March 16).

Scientific Assistant (woman not liable for National Service)—The Deputy Director, Imperial Bureau of Pastures and Forage Crops, Agricultural Research Building, Penglais, Aberystwyth (March 21).

Teacher with high qualifications in Biology—The Headmaster, The School, Dartington Hall, Totnes.

Biochemist (man or woman) in the Pathological Laboratory—The General Superintendent and Secretary, Salford Royal Hospital, Salford, Lancs.

PRODUCTION AND HOURS OF WORK

IN 1915 the Health of Munition Workers' Committee was appointed "to consider and advise on questions of industrial fatigue, hours of labour and other matters affecting the personal health and efficiency of workers in munition factories and workshops", and in 1918 the final report was published.

By means of *ad hoc* investigations and verbal evidence the Committee came to the conclusion that the long hours worked were detrimental to the health and efficiency of the workers, although they did not feel that they could definitely fix a limit for a suitable working week. Since 1918, much research work has been done and definite knowledge is now available that was lacking in 1918. For many reasons there has been a growing recognition of the importance of a reasonable working week. Before the present War some prominent firms had adopted the five-day week, and the necessity for adequate holidays and other aspects of industrial welfare had received much attention.

For research purposes the problem of hours had receded into the background, and investigations into less obvious environmental conditions, the effects of boredom, accident proneness, vocational guidance and selection, as well as problems of mental and physical health were conducted and published.

Apparently the lessons of the War of 1914–18 were not appreciated by the country in general, and so it has been necessary for the Industrial Health Research Board to publish a report* which has for its aim the consideration of some of the hindrances to maximum production in relation to the human effort.

The idea of man as a machine dies hard. For maximal industrial production there must be a regular flow of materials, the machines must be in perfect working order, and the worker of the machine must be in good health. For good health he needs, at least, adequate food, regular sleep, regular periods of leisure and reasonable conditions of work. Since the human being is not a machine he has the power to "rise above himself", to make himself by force of will produce more work than is his ordinary maximum. Hence the amazing success of emergency efforts. Unfortunately, those in authority often fail to acknowledge, except by lip service, the extraordinary as being extraordinary, and complain when the extraordinary gives way, as it must, to the ordinary. If a war were of a few weeks' duration, then little harm would be done by continued long hours, but when in this, as in the last, it is a question of years, then a steady output that can be regularly maintained is better than overwork followed by a steady decline.

This report shows the extraordinary efforts made by workers after Dunkirk. Throughout Great Britain, workers were stimulated by the state of emergency to make good the material losses incurred as a result of the collapse of France, and the effort was reflected in the production. The strength of the incentive, however, gradually waned, and fatigue and boredom could not be ignored. The time lost due to sickness, injury and absence without permission, when undisturbed by extraneous factors, varied with the weekly hours of work. It was usually reasonably low when the hours of work were less than 60 per week, but was higher and in some cases excessive when the hours were 65–75 per week. Unexplained absence of short duration rose with the increase of hours; this type of absence was due often to the desire for rest, or for a change from the monotonous conditions of the work. In almost every case holidays were followed by an increase in the rate of working. Labour wastage was high in some factories and particularly where large numbers of women unaccustomed to factory work were employed; domestic responsibilities, the difficulties of shopping and the problems of transport played a large part in this loss.

---

* Medical Research Council: Industrial Health Research Board. Emergency Report No. 2. Hours of Work, Lost Time and Labour Wastage. Pp. iv+26. (London: H.M. Stationery Office, 1942.) 6*d*. net.

The findings resulting from the investigation suggest that over an extended period the weekly hours of work should generally not exceed 60–65 for men, and 55–60 for women. The report concludes with these words: "When it is remembered that many workers lived far from the factories, and had to face air-raids when travelling to and from work; that some had lost their homes and had to sleep in improvised shelters; and that often they had to wait outside in the cold and rain because of inadequate transport arrangements, the time-keeping of the factory personnel studied deserves high praise."

That the Government recognizes the importance of such investigations as those of the Industrial Health Research Board is already apparent from the announcement, recently issued, recommending that the customary annual holiday, with a break of one day on Easter Monday, Whit-Monday and August Bank Holiday and of two days at Christmas or the New Year, should be taken. By this means it is hoped to maintain the health of the workers and also to keep up production. Nevertheless, a scientific study of the many human problems of labour is as necessary now as in the War of 1914–18, and will be still more necessary after the War.

GEOLOGISTS IN WAR-TIME

THE support given by a modern State to geological studies usually takes the form of a Geological Survey, the functions of which are, broadly speaking, twofold: namely, to prepare and publish geological maps and generally to promote the study of geology, and to collect and record geological information of economic importance relative to mineral resources and water supply. The balance between the two aspects must be delicately held, and depends to a large extent on circumstances; thus in time of war, economic work will hold first place.

Great Britain is served by an excellent Geological Survey, which has been in existence for just over a hundred years. Its headquarters are at the new Museum of Practical Geology, South Kensington, and there are branch offices in Manchester, Newcastle-on-Tyne and Edinburgh. The staff consists of a relatively small band of highly trained geologists, whose activities take them to all parts of the country, either on routine work or to undertake special inquiries. Contact is maintained with geologists in universities and similar institutions, and with mining engineers and others specially interested. During its long existence the Survey has collected a vast amount of detailed information, much of which is unpublished, but is freely available for consultation at headquarters or in the branch offices. It might be thought that the very existence of such a centralized staff of trained workers would be sufficiently well known to ensure that full use would be made of their services in the present grave times, yet there is evidence that geological knowledge is not being utilized as it should be.

Prof. H. H. Read described the position very ably in an article in NATURE of January 10, p. 39. There he showed the high importance of geological studies for industry and for agriculture in locating new and substitute sources of mineral products. It may be pointed out that such sources are not only of importance in replacing supplies cut off by the spread of war, but also that whenever home supplies can be used to replace material formerly imported, there is a saving in vitally important shipping space. Geologists are also in a position to advise in connexion with the siting of camps, factories and underground storage and shelters, and we understand that a certain amount of consultation is somewhat belatedly taking place. Here perhaps the local geologist is also likely to have valuable knowledge. Nevertheless, there is no question that, in many cases geologists have not been consulted, with resulting waste of money and effort. Prof. Read also refers in his article to the remarkable results obtained during the past twenty years in the U.S.S.R. through the employment of thousands of geologists in mineral prospecting and development.

Turning now to the direct use of geology in the Armed Forces, it is of interest to note the position in the last war as described in "The Work of the Royal Engineers in the European War of 1914–1919. Geological Work on the Western Front" (Chatham: Secretary, Institution of Royal Engineers, 1922). In 1914, the Army had no geological establishment. Very soon, however, the need for expert advice in regard to water supply became apparent, and one geologist was appointed early in 1915. In May 1916, the Australian Mining Corps arrived in France, accompanied by the late Prof. (afterwards Sir) Edgeworth David, of the University of Sydney, who eventually became geological adviser on matters connected with military mining at G.H.Q. In 1916, Lieut. Loftus Hill, assistant government geologist of Tasmania, was placed in charge of special boring operations. Shortly before the Armistice was signed, further additions were made to the geological staff at G.H.Q., which eventually totalled five, in order to cope with the demand made by the advancing forces for geological maps. In September 1918, a proposal to form a definite Geological Establishment for the British Army was put forward but was too late to materialize. Throughout the War, constant touch was maintained with Geological Survey in Great Britain. Perusal of the book referred to leaves no doubt as to the multifarious uses of geological science during military operations, yet at the recent Conference on Science and the War Effort arranged by the Association of Scientific Workers (see NATURE, January 31, p. 130), it was stated that only two geologists are employed as such in the British Army.

According to the same book, the German conception of geological aid was different. Each 'army' appears to have had a definite military geological staff. In each 'corps' there were two professional geologists, with a draughtsman, clerk and boring party, attached to a field survey company, while a somewhat similar establishment, including, however, civilian research geologists, was attached to a survey company (*Landaufnahme*) apparently at army headquarters. The value of geological information was recognized in the American Armies. In 1917, Lieut.-Colonel A. H. Brookes, for many years director of the Geological Survey of Alaska, was made geologist, and a little later an assistant geologist was appointed. Finally, it was decided to increase the number of geologists with the American forces to seventeen, most of whom had been appointed before the Armistice was signed.

A certain amount of blame for the public neglect of geology lies at the door of geologists themselves. They have tended to keep their studies too much to themselves, though perhaps the very nature of their field work has separated them from other men of science. A larger portion of blame is attached, as Prof. P. G. H. Boswell showed in his presidential address last year to the Geological Society (see NATURE, April 19, 1941, p. 459), to the educational system of Great Britain, which during the past few decades has put a premium on the study of the physical sciences and thrust geology into the background. As a result, our administrators have little or no idea of the services geologists can render, and the general public has not the background of knowledge to enable it to appreciate the deficiency.

Prof. Read suggests, in the article referred to above, that the best use that can be made of the geologist at the present time is to let him carry on his geological work. To this we would add that steps should be taken to see that, whether he works as a civilian or is absorbed into the Armed Forces, his knowledge is exploited to the full in furthering the war effort. The Geological Survey does yeoman service in answering the numerous inquiries, many of which must involve lengthy and laborious investigations, sent to it by Government departments and others, and is producing a special series of War-time Pamphlets on mineral resources and water supply, but this is not sufficient. There must be more enlightened direction from above, to ensure that wherever geology impinges on human activity, in war or in peace, the contribution it can make is recognized without delay and appropriate action taken.

'UNCLE JOHN' BRASHEAR

John Alfred Brashear, Scientist and Humanitarian, 1840–1920

By Harriet A. Gaul and Ruby Eiseman. Pp. viii+220. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1940.) 14*s*. net.

IT is appropriate that the third volume in the series entitled "Pennsylvania Lives" should be devoted to John Alfred Brashear, a poor millwright with little education, who not only became famous the world over for his genius in the construction of fine precision instruments but also, through his untiring labours on behalf of the people of his native Pittsburg, became known to them affectionately as "Uncle John" and was voted "the most distinguished citizen of Pennsylvania".

Brashear acquired at an early age from his grandfather, Nathaniel Smith, a driving passion for astronomy. It was this passion that decided him to make a telescope so that others, and particularly children, should be able to see the stars, and to see them without charge. Working alone and with no one to advise or guide him, he undertook the construction of a 5½-in. refractor. He devised methods for cutting the glass into circular form and for shaping and polishing it, designing and constructing the necessary tools and plant. With no knowledge of optics he somehow, by intuitive skill, computed the requisite curves. After two years of labour in such spare time as his long hours at the mill afforded him, and with the able assistance of his clever and courageous wife, the objective was well on the way to completion when by an unfortunate accident the crown lens was broken. Nothing daunted, another disk was obtained and eventually Brashear's telescope was completed in the year 1875.

At this time S. P. Langley was director of the Allegheny Observatory, and Brashear, critical enough to be dissatisfied with what he had achieved, ventured with some trepidation to write to Langley for an interview and to submit to him his lens for criticism. Langley's advice to Brashear was to try a reflecting telescope with a silvered glass mirror, which would not require expensive optical glass and would involve the figuring of one surface only. Thus began an association which later ripened into the closest friendship and collaboration, in the course of which Brashear assisted Langley in the invention of the bolometer; successfully made for him prisms of rock-salt, after many others had tried and given up in despair; and helped him in his pioneer investigations in aeronautics.

Acting on Langley's advice, a 12-in. mirror was completed, only to split in half in an attempt at silvering by a process, taken from the *English Mechanic*, that required heat. A second mirror was completed; silvering by various methods which were tried proved uncertain and unreliable. At length, after much experimenting, Brashear devised the process that bears his name, which he published after he had tried it long enough to be sure it was infallible. With the 12-in. telescope, he devoted much of his leisure time to spreading his enthusiasm for astronomy among his fellow-workers at the mill and the children of the neighbourhood, by showing them the stars. Articles in the local papers helped to make him known in Pittsburg. To assist amateurs who desired to make their own telescopes he began in a modest way to make mirrors and eye-pieces. The work soon grew too much for a spare-time occupation, and at length Brashear resigned his position at the mill and devoted his whole time to the business of making instruments.

Through Langley, Brashear met William Thaw, the millionaire banker, to whom Pittsburg owed many benefactions and who had endowed the Allegheny Observatory. Brashear's enthusiasm kindled the interest of Thaw, who provided him with a larger shop and new equipment. Orders successfully completed for Langley, Michelson and Rowland enhanced his reputation for high-quality workmanship and his position as the principal maker of precision optical apparatus in the United States became established. Before long, the fruitful collaboration with the Warner and Swasey Company in Cleveland, Ohio, commenced; Brashear made the mirrors, lenses and spectroscopes for the large telescopes and mountings constructed by Warner and Swasey. Orders flowed in not merely from America but also from all over the world.

Science owes much to Brashear for the discoveries that the excellence of his instruments made possible; but what he accomplished in this way was only one side of his achievement. He was greatly interested in education and all cultural matters, and in the welfare of his fellow-citizens. Endowed with a vivid personality and tremendous enthusiasm, he became the intimate friend of the Pittsburgh millionaires, Thaw, Carnegie, Schwab, Frick and Phipps. Through his influence on them he was instrumental in the expansion of the Allegheny Observatory, the University of Pittsburgh, the founding of the Carnegie Institute and the Carnegie Technical Schools and the creation of the Frick Educational Commission. He became acting director of the Allegheny Observatory, when Keeler left to become director of the Lick Observatory, and raised large funds for a new observatory; the dedication in 1912 of this new observatory equipped with a 30-in. refractor and a lecture hall, open without charge to the public, realized one of the dreams of his youth. For some years he served as president of the Western University of Pennsylvania. The demands on his time for service on various boards were very heavy, but his life was essentially one of service to the community. One of his sayings was, "There is no room for the mean man in science". A great celebration was arranged for his seventy-fifth birthday, as a tribute to the high esteem in which he was held. A sonnet was written specially for this occasion by G. M. P. Baird, from which the following lines, which well describe Brashear's character, may be quoted:

Heart of a little child, thought of a mage renowned,
Simple of life and aim, humble in victory, crowned
By loves that his heart made warm and truth that
his soul divined.

This life of Brashear is sympathetically written and gives an attractive picture of a great personality. Unfortunately, the book contains many loose or erroneous statements and many minor errors. Space permits only a few to be mentioned. The description of the Foucault test on p. 55 is unintelligible; the statement on p. 78 that "what could be known of the position of the stellar bodies, their movements and distances from the Earth, had been largely solved by the first telescopes made in America", is grossly misleading. It is not correct (p. 180) that W. W. Campbell discovered the drift of the solar system through space; this was discovered by William Herschel. The statement (p. 183) that without Brashear's help few would have known how to use what he was capable of making is surely an exaggeration. On p. 194 Brashear is reported to have said, "If you would ride from the Earth to Alpha Centauri on a train, going at the rate of a mile a minute, it would take forty-eight years. We have an exaggerated sense of our own importance." This would place Alpha Centauri at about one quarter of the sun's distance from the earth. On p. 145 reference is made to a 60-in. object glass, in process of being made for the Lick Observatory: no object glass of this size has ever been attempted. There is peculiar confusion about the Astronomers Royal and the Royal Observatory, Greenwich; on p. 110 we are told that Sir James Dewar showed Brashear round the Royal Observatory; on p. 113 reference is made to "Sir William Huggins of the Royal Observatory in England"; on p. 183 Sir William Thomson is stated to be Astronomer Royal of England, while in Chapter 14, entitled "Steel Kings and Astronomers Royal", the only British men of science mentioned are Sir William Huggins, and Dr. John Tyndall, "one of the astronomers of the Royal Institute". On p. 117, when visiting Phipps at Knebworth, the Brashears were met "at the little station of Wellwyn, between London and Sheffield". Jannsen is spelt Jannsan and Galitzin is spelt Gallitzin. But perhaps the most glaring error to occur in a book about an astronomer is on p. 70; Brashear was one evening taking to Langley a mirror that he had silvered: "As he turned up the Observatory hill he looked over his left shoulder to the white crescent of the new moon rising above the city behind him. 'That's lucky', he said." A laconic comment for such a unique celestial event!

H. SPENCER JONES.

SHEARWATER LORE

Shearwaters

By R. M. Lockley. Pp. xii+238+20 plates. (London: J. M. Dent and Sons, Ltd., 1942.) 15*s*. net.

I THINK that this is the best of the many good books R. M. Lockley has written. So good is it, so full of careful observations set down in delightful prose, that I have limited my reading of the book to a chapter a night, for in each chapter there is much food for thought.

This book describes the habits of shearwaters on the author's own island of Skokholm, but in the summer of 1939 he and his wife travelled (like their shearwaters) far to the south, and he gives vivid descriptions of that visit—made just before the War broke out—to the Berlengas Islands, the Desertas and the Salvages. On the Salvages the travellers found colonies of frigate petrels nesting, small white-breasted blue petrels with long legs. That most delicate, fragile bird in flight resembled a huge mayfly. It flew above a sun-baked isle, on which the white surf thunders from the north wind that almost always blows here. The Salvages lie some 200 miles south-east of Madeira, and on the Great Salvage the nesting burrows on the crown of the island (p. 223) are occupied the year through by a succession of nesting birds. The holes are used from April until July by frigate petrels; from August until November by Madeiran petrels; and from December until March by the little shearwater. The author makes the lonely Great Salvage materialize in the reader's mind. How fortunate he was to have worked (and slept) among its delightful birds.

But I am lingering too long on these southern isles. The book is mainly about the shearwaters of Skokholm, and the author, ably helped by his tireless and enthusiastic wife, has done valuable work in testing the homing powers of these swift-winged birds of ocean and their incubation and fledging periods. He discovered that the parents (p. 32) habitually take incubation shifts of three to five days, and (p.35) that the incubation period is 52 days, or almost seven and a half weeks. By careful observations (p. 53) he ascertained that the fledging period of the young bird is 73 days and that, like the young of the storm petrel, it is deserted by its parents some days before it makes its way, unaided, from its burrow to the sea. On occasion a shearwater would continue to brood its egg, without food or relief, for a much longer period than five days. One of the birds nesting beside the author's house on Skokholm, which he named Adam, once brooded the single white egg for ten long days and nights in the burrow without being relieved by his mate. But when she took over, Aida (the mate) gave him a good spell of freedom, for she in her turn brooded for seven days without relief. Adam then brooded the egg a further nine days, losing in that time 2 oz. in weight.

From ringing experiments the author gradually realized the astonishing fact (p. 126) that the shearwaters of Skokholm actually fly to the Bay of Biscay to feed during their days off duty. That double flight in a straight line is 1,200 miles, but is well within the power of so strong a flier as a shearwater. This interesting discovery puts me in mind that I have often seen shearwaters on summer days moving south through the Sound of Mull. These, I take it, are birds which are nesting on Eigg, and it is not beyond the bounds of possibility that they too have their feeding-grounds in the Bay of Biscay.

It is no wonder that the young shearwater grows slowly, for the author has proved by experiment that on moonlight nights (it is never fed by day) the parents do not visit it. In very fine clear weather it may therefore go hungry for the best part of a week.

The recovery of various birds in Bay of Biscay waters at a time when they were actually nesting on Skokholm makes interesting reading. One of the most remarkable records (p. 124) was the discovery of a ring in the stomach of an angler fish weighing 40 lb.

The homing experiments were begun on a small scale. A shearwater from Skokholm was released at Start Point at 2 p.m. one summer day. At 11.45 p.m. the same night the bird was brooding its egg on Skokholm—and the egg was warm. That flight was a distance in a straight line of 225 miles. In Chapter 14 the author describes how he later took with him two shearwaters from Skokholm and released one 100 miles south of the Faroe Islands, the other just off those islands. When he returned to Skokholm he found both birds in their burrows, roughly 700 miles to the south. But the most remarkable homing feat was accomplished (p. 178) by a shearwater which was liberated on the shore at Venice (it had been sent by air) and returned to Skokholm, a distance of 3,700 miles by sea, in 14 days. The author seems to think it more likely that this shearwater returned overland for a part of the distance, but my own belief is that it must have kept to the sea throughout. To the shearwater, as to the gannet, the ocean is its home, and to travel over hill and plain, far from any feeding-ground, would be, I submit, foreign to its nature. I feel confident that the bird travelled by sea throughout. That is a remarkable flight: 500 miles south-east down the Adriatic, then south-west to the Straits of Messina, thence west to Gibraltar and north to Skokholm.

Since the shearwater's home is the sea, I think, therefore, it is not surprising that the majority of the birds released on the Alps (pp. 183, 184) in the summer of 1939 failed to make their way back to Skokholm. That the shearwater is a good flier even from the first is proved by the feat of a nestling which, ringed on Skokholm on September 3 before it had tried its wings, was discovered (p. 138) three days later on the coast of France.

On p. 49 there is an interesting account of how shearwaters at night climb a rock in order to 'take off' into the wind, "using legs, wings, and hooked bill, all three, to get to the top". Many birds, using the rock in this way for many generations, have worn a grove in the soft sandstone.

This book is a rare combination: exact scientific record combined with enthralling narrative written in simple, vivid English. Here is (p. 142) a literary gem:

"It had been a brilliant day with a strong north-west breeze against which a migration of swallows struggled northwards across the island, their white breasts skimming low over the yellow primroses, the white sea-campion, the first bluebells, and some early sea-pinks. A peregrine falcon, which for days had been attacking the small birds and the puffins, rose upon the wind vertically, and climbing higher and higher, dwindled and vanished against the infinite blue of the sun-filled sky. Towards evening heavy rain clouds came up out of the west and covered the setting of the young bow of the new moon. The wind eased and the whole sky became suddenly dark. That night was black and starless, and full of shearwaters."

I like, too, his description (p. 6) of the calling of oyster-catchers as a "whickering". That exactly describes the sound.

The book is well illustrated, and is one which will transport the reader, however much he may be engrossed with the cares of these grim days, to the restful beauty of Nature, ever-changing and ever-young. SETON GORDON.

MEDICAL THEORY AND PRACTICE

The Advancing Front of Medicine

By George W. Gray. (Whittlesey House Publication.) Pp. viii+425. (New York and London: McGraw-Hill Book Co., Inc., 1941.) 3 dollars.

THE medical man who is called in to treat disease is, in most cases, faced with a well-nigh impossible task. He is asked to remedy the defects of an organism, the normal working of which he does not understand. He cannot understand its working until, for one thing, chemistry and the application of chemistry to physiology have advanced further. It is the expedients and ingenuities used and the successes achieved in this task of treatment that Mr. Gray describes; with enough about the nature of diseases to make his description intelligible.

His account of recent advances is vivid and well balanced. For example, in the chapter on cancer he insists that the type of treatment must vary with conditions; he holds up no treatment as a panacea, but points out that any wholly satisfactory treatment must depend on a fundamental understanding of the nature of cancer. He indicates the wide range of medical research, from vitamins to brain potentials, from the inheritance of hæmophilia to the cycle of the virus of swine influenza, through lung worms and earthworms. But would a layman, reading this book, realize what difficulties have been overcome or how much success has been a matter of lucky shots?

One of the most spectacular achievements has been the discovery of the sulphonamide drugs. The difficulty has been to find something that will kill bacteria, once established in the body, without injuring the even more vulnerable host. Specific antisera, one of the natural defences, seemed promising; but, on the whole, they have been disappointing. First it had to be learnt that antisera, to be effective, must contain certain antibodies against the right constituent of the right type of the species of bacteria incriminated. Even now, with these requirements satisfied, it needs statistical analysis to prove the efficacy of sera in the treatment of pneumonia. It might seem possible to make some synthetic chemical with specific actions similar to those of antisera; but our chemistry is not yet advanced enough to solve the secret of these specific actions. So chemists have synthesized drugs in the hope of finding one that is effective; pathologists have tested them on animals and if they seemed successful they have been handed over to physicians to try on human patients. In this process the chemists of the I. G. Farben-Industrie made an azo-dye from *p*-aminobenzene-sulphonamide and handed it to Dr. Domagk to test on animals. Domagk found that the dye protected mice against streptococci. Human beings were then treated with remarkable success. Later it was found that the sulphonamide half of the dye alone was active. The development of this drug has not been based on theory; theories have limped far behind the discovery.

It was Whipple's demonstration that liver is particularly effective in curing anæmia, produced by bleeding, that led Minot to try the use of liver in the treatment of pernicious anæmia. But it seems that the effect on pernicious anæmia is entirely different from that found by Whipple; Minot could not have inferred the amazing cure of pernicious anæmia from Whipple's experiments. It was a lucky shot. As for the shock treatments of schizophrenia, they have much the same theoretical basis as the treatment of a watch by poking with a pin.

This insistence on the importance of appreciation of fundamentals does not imply any underestimate of the value of treatment or of the difficulties that practising physicians and surgeons must overcome. But, without this appreciation, it is not possible to realize the tremendous odds against which the medical man puts up a gallant fight. Mr. Gray's long list of brilliant partial successes may lead people to expect too much, too soon. Could he not have shown how much his front-line fighters are handicapped by lack of supplies and support from the rear in the form of fundamental theories on which treatment can be based?

A few of the faults inevitable in a compilation of this type have crept into the book. Some of the names quoted carry little weight; tuberculin is not a serum; the amounts of vitamin B_1 in meats (p. 45) are incorrect; Prof. J. Mellanby is not "of Oxford".

AN ORIGINAL APPROACH TO THE PROBLEM OF TUMOURS

The Problem of Tumours

The Application of Blastogenic Agents to Ciliates; a Cytoplasmic Hypothesis. By J. C. Mottram. Pp. vii+91. (London: H. K. Lewis and Co., Ltd., 1942.) 7*s*. 6*d*. net.

THE first part of this book deals with changes in form and behaviour of ciliates exposed to agents which increase or decrease the viscosity of the cytoplasm. A wide variety of physical and chemical agents cause similar effects, and, apparently, anything which makes the cytoplasm more viscid tends to inhibit complete fission, so that multinucleate cells are formed. Among other agents, the carcinogenic hydrocarbons can produce this result and thus give rise to clones of abnormal cells. Smaller doses have the opposite effect, and cause increased rate of division, but no recognizable abnormality in the daughter cells. A short review of the literature on abnormality in Protozoa is included. The important point is made that once abnormality has been induced, it may be perpetuated in the absence of the inciting agent.

Another point of greater interest is, that only a small proportion of ciliates in a culture react by recognizable abnormality, but that these cells can transmit the tendency to abnormality indefinitely: whether the abnormal cells overgrow or are overgrown by normal cells in mass culture depends on their relative rates of fission.

These and many other experimental observations are adduced by Mottram in support of the contention that the behaviour of these abnormal Paramecia is analogous to that of tumour cells in mammals. Having presented these facts, he invites the reader to answer this postulate for himself, but makes it clear that he thinks the answer should be affirmative. The gene mutation theory of cancer is briefly discussed and dismissed by arguments which appear to the reviewer to be feasible but not conclusive. A short account is given of an interesting chance infection of a culture of Aspidisca by an unidentified virus, which could be recognized as inclusion bodies in the cytoplasm, and which gave rise to abnormalities in morphology and behaviour similar to those induced by blastogenic agents. Unfortunately, the disease was fatal, and attempts to recover the virus and to infect new cultures failed.

Despite the obviously great differences between unicellular animals and the tissues of mammals, Mottram has assembled a remarkable number of analogous findings in the behaviour of these cells under a wide variety of adverse conditions. He anticipates the criticism "that to draw analogies between the reactions of Protozoa and Metozoan cells is fallacious"; but, whereas these analogies are based on observed facts, some of the assumptions in the postscript are much more open to criticism. However, the author is careful to keep his facts distinct from his theories, and his account of a most original approach to the problem of tumours will be enjoyed by most research workers.

The text is freely illustrated with excellent black and white drawings, and a photographic frontispiece, and there is a bibliography of 103 references.

P. R. PEACOCK.

The Birds of the Liverpool Area

By Eric Hardy. (Merseyside Naturalists' Association Handbooks, No. 1.) Pp. 279+10 plates. (Arbroath: T. Buncle and Co., Ltd., 1941.) 8s. 6d. net.

FIELD ornithologists will appreciate this publication, first for bringing within the confines of a single volume a mass of records hitherto scattered among numerous publications, and secondly for its list of localities where the bird-lover, month by month, can view many of our common species. Part of the preface could, with advantage, have been omitted, as the author devotes it to criticisms of local societies, inappropriate to any scientific work. There is a brief list of local ornithological collections and a short account of Wild Bird by-laws.

The opening paragraphs of the chapter on "Bird Movement and Migration", while containing much that is useful and interesting, are likely to irritate the reader by obscurity of presentation. The chapter on "Bird Census" is not convincing and the author's figures are unbelievably accurate. On p. 48 he states: "The Liverpool Census for 1935 showed 95,000 House-sparrows, 27,000 Starlings, 1,680 Wrens, 1,310 Greenfinches, etc.". Ornithologists who have essayed a bird census, even in a relatively small area in the country, know how difficult it is to arrive at a satisfactory assessment. A census of starlings or sparrows in a large city such as Liverpool will be regarded by most competent ornithologists as unreliable. In compiling the hundred pages of notes on the birds of the Liverpool Area much painstaking search of records must have been involved, but the author's own work would not have suffered by less frequent reference to himself. The volume is illustrated with two maps, one sketch and thirty-one photographs, of which those of the long-eared owl and the lapwing in flight are indeed good. R. K. PERRY.

Transients in Electric Circuits

Using the Heaviside Operational Calculus. By Prof. W. B. Coulthard. (The Specialists' Series.) Pp. viii+203. (London: Sir Isaac Pitman and Sons, Ltd., 1941.) 25s. net.

IT has been said by an eminent American engineer that whereas problems in transient phenomena can only be solved by the application of the calculus, the terrors which this branch of mathematics holds for many engineers have largely been removed by the substitution of the Heaviside operational calculus. Transients may be controlled or fortuitous, but in either case the transient response of a network to excitation can be solved expeditiously and with minimum labour by the technique which has been built up around Heaviside's original methods.

The book under review presents a modern version of this technique in its application to the study of electric circuits consisting of static networks, rotating machines, and component structures. Circuits having both linear and variable parameters are analysed, as well as those which can be regarded as lumped on one hand and in which expansion yields negative powers of the differential operator p, and smooth on the other hand, wherein expansion gives fractional positive powers of p.

Fourier series and integrals are discussed in order to throw further light upon operational methods and to show that the integral yields a long list of operators and their equivalences.

The book is a particularly valuable one to the research worker and to the mathematically inclined engineer.

Nature Abounding

Edited by E. L. Grant Watson. Pp. 350. (London: Faber and Faber, Ltd., 1941.) 10s. 6d. net.

EARTH, air, fire, water, these were the elements as conceived by the philosophers of other days, and under these heads Mr. E. L. Grant Watson, in the present work, has assembled an unusually readable and varied prose selection, representative of the interest with which Nature, to the seeing eye, abounds. He has chosen widely and well. Nature's appeal is for the many, and the compiler has sought his materials, not only in the writings of professed naturalists, explorers and physicists, but also among those of sportsmen, novelists, essayists, gardeners, farmers, and, not least, of the ordinary man. Thus passages from Darwin and Wallace rub shoulders with not less informed observations by Hardy the novelist, Tomlinson the sympathetic voyageur, or Borrow the wayfarer. As he turns the pages, the reader will meet many old and expected friends: Fabre, Hudson, Herman Melville, Izaak Walton and others, and among newer ones, Frazer Darling, Kenneth Graham and Sir James Jeans, to take only a few at random.

The knowledgeable reader, with critical intent, may perhaps peruse this book with the view of testing the compiler's selection against his own recollection of outstanding passages in classic works. Of course, he will find omissions and an unwelcome abbreviation of his own particular favourites, but as Mr. Grant Watson points out, the literature of exploration, travel and natural science in its several branches is so extensive that there can be no question of compiling a complete work. But books of this nature are all too rare, at least so far as the literature of science is concerned, and it seems not impossible that they may have a considerable future, particularly for the specialist worker whose time for general reading is necessarily limited. More is the pity that war-time conditions should condemn such noble text to such indifferent paper.

Oriri

By Marie C. Stopes. Pp. ix+27. (London and Toronto: William Heinemann, Ltd., 1940.) 3s. 6d.

THIS considerable poem has already been reviewed, and favourably reviewed, in various literary journals. It is the love story of a man and a woman in a setting in which objects of Nature, earth, trees and flowers, are harmonized to the central theme. In the Argument, the author tells us that: "Interwoven into the tale is a crystallization of most of what matters fundamentally in the sciences of geology and physiology, in the art of love, and in religion." The poem has, indeed, a scientific content, but so pervading is the artistic sense, so effective the condensation, that the work, which may well be considered as briefly epical, makes its appeal, as the author intended, as poetry.

> "Time's sands shine dripping over
> With burdens of delight
> Garnered from all the past:
> Again the bright sea sparkles on this hill
> And slowly specks of life shed through its blue
> Their fragile vestures, piled to build a land."

Not the least unusual feature of this remarkable work is the brief appendix in which the scientific basis for the imagery used is indicated.

INDIVIDUALITY AND SCIENCE*

By DR. A. F. BLAKESLEE
Director, Cold Spring Harbor, New York

IN looking over my past research activities, the one idea which impresses me most is the individual diversity among living organisms. Our first published investigations had to do with a group of lower fungi which can be included in the name of bread moulds. Among these we discovered that growths which looked alike might differ in sex and in a wide range of chemical responses.

Another example of cryptic chemical differences was furnished by the black-eyed Susan (*Rudbeeckia hirta*). Two races which had yellow instead of purple cones we found could be distinguished by use of strong potash solutions. The treatment turned the cones of one race black and those of the other red.

These examples have to do with innate differences between individuals. Let us consider some examples of differences in which the environment appears to be the controlling factor. One variety of corn has red kernels at the ends of the ears where they are exposed to the sun but white kernels where they are covered. Both the red and the white kernels when planted, however, gave the same kind of offspring. What was inherited was the capacity to become red in a light environment and white in a dark environment.

I used to ask my students to find two apple leaves which were alike. They would start with enthusiasm, but soon would come to realize that two leaves exactly alike could not be found if one used as a simple criterion of identity the possibility of having the two leaves match with all their indentations when one was superimposed upon the other. I would point out that the general pattern of the apple leaf in distinction from that of an oak, for example, was due primarily to its hereditary constitution but that the wide variations in size and shape of leaves and the arrangement of teeth on their edges were modifications of the pattern induced by differences in the environment such as the position of the developing leaf in relation to light and shade, vigour of the twig, its position in the developing bud and other possible factors in internal environment.

With these considerations in mind it is not difficult to realize that probably no two trees in orchard or forest can ever be exactly alike, since in addition to the modifications brought about by variations in environment we have the modifications brought about by differences in hereditary constitution.

Although we can influence the character of organisms through the environment, it is generally believed that we have no control over their heredity. This is not entirely true.

Records this month on seedlings of jimson-weed which had grown from seeds buried for thirty-nine years in soil at the U.S. Department of Agriculture in Arlington seem to be showing an increased rate of mutations. We cannot predict, however, the exact types of hereditary changes that will be induced by ageing and other stimuli. In some cases in the jimson-weed, however, we have used mutated chromosomes with which to synthesize new pure-breeding types with predicted characteristics. By attention to the total number of their chromosomes we have reduced their ability to hybridize with their parental types and hence feel justified in calling them synthesized new species.

By one method we have succeeded in exercising conscious control over heredity, and are able to predict with reasonable accuracy the characteristics of the new types induced through doubling their chromosome number by means of colchicine. In our own and other laboratories new species have been produced by doubling the chromosome number of sterile species hybrids, and new species are known to have been produced by this method in Nature.

In many biological problems affecting human beings, science has had to look to botanists to lead the way. I need to remind you only of the original discovery of the mechanism of heredity by Mendel from his work on garden peas and its later independent rediscovery by three botanists. My interest in human individuality came from my experience with plants. It all started from a botanical problem in 1917 when we were trying to classify the colours of a segregating pedigree of Verbenas. A particular pink-flowered form was very fragrant to me but had absolutely no odour to my assistant. On the other hand, a certain red-flowered Verbena was fragrant to him but not to me. Some of the people in our laboratories agreed with me and some with my assistant. Only a very few found fragrance in both kinds of flowers.

Phenyl-thio-carbamide is a good reagent with which to show innate differences between people. Some of those we have tested need to have the solutions of this reagent more than eight thousand times as strong as others in order to taste it. The inability to taste the commercial crystals is inherited like blue eyes as a Mendelian recessive character; but different grades of taste acuteness have also been shown to be inherited. Numerous tests with other substances only emphasize the wide differences between people in their taste reactions.

The individual reactions of taste are dependent primarily upon innate hereditary factors, and the environment appears of relatively little importance. With smell the condition is quite the opposite. Probably even wider innate differences exist between people in their acuteness of smell than of taste, but environmental factors in abundance prevent the full expression of these hereditary differences. Thus age is a potent factor progressively dulling the sense of smell. A considerable number of people have lost their sense of smell entirely. Temporary conditions of a person, such as a cold in the head, may adversely affect his ability to smell. After being exposed to an odour for a time it becomes no longer perceptible. Olfactory fatigue apparently may be produced even by concentrations too weak to be detected. This is probably the explanation of asphyxiation of people by gradually increasing concentrations of gas which they never detected.

The sense of smell does not play as important a part in man as in many of the lower animals in bringing us information about the external world. There is not a negligible number of people, however, who can distinguish different individuals by odour in the same way in which dogs can distinguish individuals by scent alone. This power is more frequent in children but is often retained into adult life when it is generally concealed on account of the social taboo against speaking of personal odours. Several parents have informed me that certain of their children when young by smelling a handkerchief they had picked up could tell to which member of the family it belonged, but this ability had been lost after they had grown up.

---

*Substance of the address of the retiring president of the American Association for the Advancement of Science, delivered at Dallas, Texas, on December 29.

Associations are especially powerful with the sense of smell, but they exist with all the senses. So long as we live we are building up associations and developing our personality through reactions with our environment which express themselves in likes and dislikes. Likes and dislikes are important determiners of our behaviour.

The examples just given of the influence of heredity and environment have been taken from the senses of taste and smell. All the other senses are similarly subject to internal and external influence. I need only mention the innate differences in musical discrimination disclosed by Seashore and the progressive decrease, under the environmental influence of age, in the pitch or number of sound vibrations one can distinguish at a given intensity. There are a host of other responses which contribute to human individuality. Among these are the blood groups, the natural and acquired susceptibilities and immunities to disease and chemical substances, the allergies and the reactions to hormones and vitamins. The Binet and other mental tests have disclosed great differences between individuals in mental equipment.

Votes for Titles in Relation to Position on Ballot, Lancaster, Pa., January 30, 1941

*Five titles were listed in different orders on five ballots A to E.

Numbers under each position are percentages of votes cast for given title on the ballot indicated by letter at right of figure.

Males: Ballot A was voted 48 times; B, 54 times; C, 52 times; D, 57 times; E, 38 times.

Females: Ballot A was voted 46 times; B, 35 times; C, 43 times; D, 38 times; E, 46 times.

It will be granted no doubt that there are great differences between people in their sensory judgments regarding the world in which they live and that these differences are influenced in varying degree by factors of both heredity and environment. Is this true of man's mental and spiritual judgments? I believe it is even more so. A few simple examples may be given.

At the end of a meeting held at Lancaster, Pa., the audience was asked to select the best title among five which had been suggested for the lecture just given (see table). It might be thought that since all had heard the same lecture, there would have been considerable unanimity in preference. This was not the case, however. Though two titles had more votes than the others, each of the five titles was preferred by a considerable number. Here again we may be reasonably sure that factors of both heredity and environment did influence the mental judgments regarding the best title.

The Supreme Court of the United States is composed of outstanding minds. Their honesty is unquestioned, and they are freed from even the unconscious pressure of political expediency. Here, if anywhere, we should expect unanimity. The Supreme Court, however, from its early history had rendered numerous decisions by a divided vote and in many instances, including some of the most important cases, by a majority of only one. With its broadly changed complexion since early New Deal days, one might expect less diversity in judgment at the present time. This does not seem to be the case judging from a recent news report of the first two decision days of the present term. Within two weeks there were brought in three 5-to-4 and two 6-to-3 decisions. None of the justices during this time had failed to enter at least one dissent and all except two had more. We cannot here attempt to analyse the elements in these differences in judgments. Such blanket terms as liberal and conservative suggest the influence of innate disposition and also of such environmental factors as advancing age. If we remember our experiments with taste and smell we may agree that judgments of drinkers regarding the taste of beer and judgments of the Supreme Court regarding issues of law cannot help differing because men both are born different and have differences thrust upon them by their environment.

Differences in expression in art, music and literature can likewise be attributed to influences of heredity and environment. I have personally been interested in studying the manner in which trees have been used in art. Styles in method of representation are evident, but the artists differ in the way in which trees appeal to them. Some are interested in individual trees, others in groups. Some prefer trees in the foreground, others in the background or in the middle distance. There are differences also in the species of trees which different artists like best.

We have given examples of differences in plants and animals such that no two individuals are exactly alike and have classified the causes of these differences into the interacting factors of heredity and environment. We have shown that both heredity and environment are likewise responsible for the diversities in man, not only in his physical structure and sensory reactions but also in his mental and moral judgments. Every thought and act of our lives is influenced by these two factors. Man has used his knowledge of heredity and environment to mould plants and animals to his personal advantage. Can this be done with man himself? To some extent, yes, but the way is not so clear.

I know of no adequate evidence that man to-day is a better animal physically or mentally than at the dawn of history. While man's biological evolution during these five thousand years and more has seemed to lag, and at the present time has appeared to many to have been thrown into reverse, man's environment has changed markedly even within our own lives. Conscious control of human heredity, though a desired goal, will at best be slow even if our genetic knowledge were adequate for the task. Changing man's environment gives promise of more rapid betterment of human individuals, and in this effort we are far from reaching diminishing returns.

But the facts of individuality and the relative influence of heredity and environment upon personality must be carefully estimated in any rational campaign for permanent social betterment. Such knowledge has power to revolutionize our ideals and practice in social and religious justice, charity and education, methods of legislation and forms of government. Methods of education, for example, have been severely criticized for mass regulations which fail to take adequate account of individual excellences. Similar criticisms come from the so-called exact sciences, mathematics, physics and chemistry, against the difficult, less exact biological sciences, botany and zoology, and some would even deny the name of science to those most difficult studies of man's social behaviour. For years the educational world has been struggling with the problem of how best to deal with the increasingly recognized differences in mental ability, differences which, like those we have found in taste reactions, are of two kinds: a difference between general marked ability and general mediocrity and a difference between ability in certain lines such as mathematics, science, art or literature.

I recently wrote to the sixteen living past presidents of our Association and asked them if they could satisfy the enclosed New York State requirements for teaching in the State secondary schools. Not one of the past presidents of the American Association for the Advancement of Science would be allowed to teach science in a New York high school without further preparation since none had taken the required instruction, which included such subjects as the psychology, history, philosophy, principles and practice of education. One past president properly remarked that not all presidents would have been good secondary school teachers. It is a fact, however, that more than a quarter have had secondary school teaching experience, but could not now qualify under present requirements. This is not at the present time a serious deprivation of the freedom of these men, but some believe the State methods of selecting teachers place undue emphasis upon relatively unimportant requirements. Some educators have told us that, in the balance between method and subject-matter they believed the pendulum had swung too far towards method.

Blanket regulations may make for ease of administration, but too great uniformity may preclude the assets of individuality. Uniform laws throughout the States would have certain advantages, but they might not be equally well adjusted to local environments and might prevent profitable experiments in local government. The increased means of communication throughout the world appear a mixed blessing. They tend to standardize our thoughts and behaviour in a common mould, but at the same time to decrease the material expressions of individuality available for social evolution through natural selection.

Opposition to totalitarianism is not merely because it attacks man's rights but also because it suppresses his personality. Individuality is the kernel of democracy, the biological basis of the struggle for freedom. When we fight for individuality we fight on the side of Nature. Recognition of individuality and all that it implies especially concerns us as men of science. Even if science were again persecuted and driven under cover, as it was in the Middle Ages, there would still be some brave inquiring minds. But science cannot flourish without freedom of thought and its expression.

Why do I emphasize the value of individuality to science? Because I believe science is the great hope of mankind.

In speaking of science and men of science it should be clear I am not confining attention to the professionals. Whoever by observation or experimentation is responsible for increased knowledge of the world in which we live is a servant of science and contributes to the welfare of mankind. In this connexion it is appropriate to mention that in Colonial times keen observers had discovered the causal connexion between barberry bushes and infestations of wheat rust and had passed laws in Massachusetts for the eradication of barberries long before botanists learned that a necessary stage in the life-cycle of this rust is confined to the barberry.

Science is under fire for the suffering brought about by its applications, especially in the present war. Science is in no position to disavow its responsibilities in the problems of peace and war. As in epidemics of disease due to ignorance of medicine we need not less but more medical knowledge, so in seeking a cure for the scourge of war we need not less but more science. The remedy we trust may ultimately be found by that most difficult of all biological sciences—the study of motives and human behaviour. Science can reply to its critics that the applications of science are merely tools which men with good or bad motives use for their good or evil ends. The same can be said of printing. Even if we admit the responsibility of science for deaths due to its applications we will find that its applications have brought about even greater savings of life. The legend to a reproduction of the title page of Jenner's paper on vaccination published in 1798 reads: "The application of the facts presented in this paper has probably saved more lives than the total of all lives lost in war." The statement is easy to believe, since it has been estimated by Haggard that in the hundred years preceding Jenner's paper, sixty million people in Europe died of smallpox.

In war itself science has not been alone destructive, as may be seen from figures supplied by the Surgeon General's office regarding the annual death-rate per thousand in the United States Army for the Mexican War, the Civil War and the first World War. Deaths due to battle injuries increased from 15 per thousand for the Mexican War through 33 for the Civil War to 53 for the World War. The death-rate due to disease, however, decreased from 110 through 65 to 19 for the World War. The net result is that the total death-rate actually declined, from 125 in the Mexican War through 98 in the Civil War to 72 per thousand in the World War. It is a satisfaction to feel that though implements of war have increased in destructiveness, those who are fighting to preserve our free way of life may not be subjected to greater risks than our forefathers assumed when they too fought for their country.

It can scarcely be emphasized too strongly that it is not man's material comforts nor even the alleviation of his physical pains which are the greatest gifts of science to mankind. Science has freed men's minds. Foremost among liberating ideas is the belief that there is order and law in the universe and that this order can be discovered by questioning Nature herself. Such belief was rare in the Middle Ages when processes of Nature were generally attributed to supernatural causes: winds and storms to demons, comets and epidemics to the wrath of the Almighty towards a sinful world, and investigations of Nature were persecuted by both Church and State as Satanic magic and sacrilegious questioning of the acts of God. The Copernican theory widened our physical horizons and showed our earth as a tiny speck in a universe of worlds. The theory of evolution brought a unity to our ideas of the organic world. The discovery of the mechanism of inheritance allowed an evaluation of the contributions of heredity and environment to the personality of individuals. The experimental method with adequate controls is the most valuable tool science has yet developed. Its understanding and use in daily life would mean more than all the scientific facts that schools can teach.

Science has helped to free man's soul. It has broadened the horizons of religion and given it a new point of view away from the old intolerant, materialistic theology when men sought their own salvation from selfish hope of heaven or fear of hell and persecuted or even killed those who did not conform to the authority of orthodox beliefs. Elimination of such incumbrances has left to religion a freer field for the cultivation of its great spiritual values.

Science has banished much of ignorance and superstitution, but much remains. Recently in New York's Pennsylvania Station I purchased seven different magazines on astrology. One of them, and this not the best seller according to my newsdealer, I found had a monthly paid circulation of more than 132,000 copies. The readers of these astrological journals are part of our democracy and help to form the policies of our Government. Other examples need not be given to show that the scientific method has not yet saturated our land.

If we consider past efforts to better mankind, it is clear that good intentions are untrustworthy criteria of service to humanity. The biblical criterion—"By their fruits ye shall know them"—is biologically sound doctrine and still the best test. The attempts to suppress independent thought and study of Nature in the Middle Ages, and up to the not distant past in our own country, were inspired by noble motives, but they put civilization back by many centuries. The Crusaders had a lofty purpose but a trivial objective: the capture of an empty tomb, with all too slight appreciation of the teachings of Him whom the tomb had held.

During the plague of the seventeenth century when twenty-five million people or a quarter of the population of Europe died of this dread disease, there were doubtless, as there should have been, hospitals and other organized efforts to minister to the sick and dying. We can imagine the scant attention that would have been then paid to a request for a grant for a scientific study of the life habits of such creatures as rats, fleas and the wriggling animalcules which Leeuwenhoek discovered at about this time in drops of putrid water. Yet our knowledge of rats, fleas and bacteria is one reason why centuries later pest hospitals are not found in London and we no longer dread the plague. The illustration given is an example of the unsuspected value of knowledge in apparently unrelated fields. Many other examples could be given of the service of science to human welfare, a service which is often indirect. The ancients used human sacrifices to ensure bountiful harvests. Now we use commercial fertilizers for this purpose and find them more efficient. In the old days people fought yellow fever and smallpox by church rites and religious processions. Now we fight these diseases by killing mosquitoes and by vaccination. Formerly thousands of people were executed on the ground that they were witches. Science has proved that witchcraft does not exist. It would be difficult to give from history as striking examples of success in direct efforts to improve the condition of mankind without the aid of science.

Knowledge is power also in our efforts towards human betterment. We must learn the facts about the environment in which we live if we wish to adjust ourself into harmony with it. Efforts against Nature are doomed to failure despite high motives. It is for this reason we believe that in a rational programme for human betterment science—the free search for truth—is in the long run the best investment. If what I have said is true, it lays upon us all, both scientist and layman, a responsibility for the advancement of science, free and unhindered as a service to mankind. Think where we would have been now if in the Dark Ages men like Copernicus, Galileo, Albertus Magnus, Roger and Francis Bacon among other inquiring minds had been able to carry on their scientific investigations in an atmosphere of intellectual freedom. Our most difficult sciences might now have reached the stage occupied by biology, for example, and we might already have found a remedy for our present sick civilization.

How can science best be fostered? I need offer only a few suggestions.

Science, in common with all intellectual pursuits, needs tolerance, freedom from restraint and a recognition of the value of individuality. Men differ widely in their capacities for research. A great need therefore in the advancement of science, as of other intellectual endeavours, is to devise means for discovering the exceptional abilities at an early age and giving such abilities exceptional opportunities in order that their span of effective service with its social values may be prolonged.

The public, whom science serves, knows all too little what science really means. The magic and gadgetry of scientific applications rather than the methods and ideals of science make the great appeal. Yet the ideals and methods would help society reach judgments on the basis of ascertained facts rather than through emotional appeal and personal profit, and would transform our daily lives if universally applied. Think what a chance would come if our representatives in legislative halls should open each session with the prayer of Huxley: "God give me strength to face a fact though it slay me"—and really mean it.

A common comment of a layman after visiting a laboratory and having research explained to him is: "What great patience scientists must have!". The real thought appears to be how can reasonably intelligent men, as men of science seem to be, be content to spend time in such trivial and uninteresting details. The layman seems to feel as he might in watching a small child picking up little white pebbles laboriously one by one and putting them into a bucket, and then taking them out again one by one in the same painstaking manner. Yet this same layman sees reason in taking a stick and whacking a diminutive white ball over a field, alone or in company with others, and each time he gets it into a little sunken bucket he takes it out again and whacks it to another bucket of the same dimensions. Science as well as golf is a sport to those who play the game and there is a chance of some bit of human value when the game is done.

In the promotion of human welfare through the advancement of science, men of science and the public have a common interest and may have a common share. I believe the American Association is especially adapted to furthering these common interests and could profitably undertake a study looking towards the development of a more effective programme that would serve the aims of man of science and layman alike.

In the United States as nowhere else patrons of art, literature and science have made investments in human good. The yields in benefits secured have varied much, but sometimes have been slight because the investments have been unsound. We trust that those of philanthropic intent who wish to promote human welfare through the methods of science will subject their donations to as careful checks as they would a financial investment in order to ensure a profitable yield in the way of scientific dividends. A newly established National Science Fund is in position to serve as a clearing house for advice on the probable scientific dividends which may be expected from investments in science.

Although we do, each of us, live in different and more or less separate worlds of our own, I trust we shall ultimately be able to acquire a social organization as orderly as the constellations of other worlds. In our fight for individuality and freedom in this War and in the peace to come, I do not despair. The experimental method has demonstrated we must use force without stint to show that freedom and political morality as well as personal honesty really pay. We still cherish the faith that the free search for truth by the methods of science has power to rebuild the world and will prevail.

SRINIVASA RAMANUJAN*

By PROF. E. H. NEVILLE
University, Reading

SRINIVASA RAMANUJAN was a mathematician so great that his name transcends jealousies, the one superlatively great mathematician whom India has produced in the last thousand years. He was born at the village of Erode in Tanjore on December 22, 1887. His parents were Brahmins of high caste, but very poor, and without any means of direct access to influential people. Srinivasa's mathematical ability was soon recognized at the high school at the neighbouring town of Kumbakonam, which he entered at the age of seven. We are told with what delight the big sixth-form boys found at the bottom of the school a youngster who was ready to do all their hard sums for them, and with what mixed feelings he read in their books theorems which he had discovered for himself. In 1903, a few months before he left the high school with a scholarship to the Government college in the same town, there came into his hands a "Synopsis of Mathematics", a book containing the enunciations of some six thousand theorems, for the most part without proofs, and Ramanujan set to work systematically to establish the results. Geometry did not appeal to him, but in algebra and calculus he found himself in a magic world, in which he lived for the next ten years. In proving one formula he discovered many others, and he began to compile a note-book, the first of the note-books which afterwards became famous.

Unfortunately, Ramanujan lived too completely in his new world. College regulations could secure his bodily presence at a lecture on history or physiology, but his mind was free, or, shall we say, was the slave of his genius. We know now that to describe one hour which Srinivasa Ramanujan spent on mathematics as mis-spent is absurd, but to the college authorities he was just a student who was neglecting flagrantly all but one of the subjects he was supposed to be studying. The penalty was inevitable: his scholarship was taken away, and he was told that he must repeat the year's course. So he ran away, and what he did and how he lived for the next few years is not on record. He returned to college for a short time, but failed to secure any academic qualifications.

Away from college, Ramanujan's wants were few, and for five years he was able to satisfy them without interrupting his investigations. But in 1909 he married, and needed definite employment. His unfortunate college record was a serious obstacle, and he obtained introductions from one to another of three Indian mathematicians, Ramaswami Aiyar at Tirukoilur, Seshu Aiyar in Madras, and Ramachandra Rao at Nellore, to whom in turn he produced his note-books as evidence that he was not the incorrigible idler his failures seemed to imply. Ramachandra Rao has given an account of Ramanujan's first interviews with him:

"Several years ago, a nephew of mine, perfectly innocent of mathematical knowledge, spoke to me: 'Uncle, I have a visitor who talks of mathematics. I do not understand him. Can you see if there is anything in his talk?' And in the plenitude of my mathematical wisdom, I condescended to permit Ramanujan to walk into my presence. A short, uncouth figure, stout, unshaved, not over-clean, with one conspicuous feature—shining eyes—walked in, with a frayed note-book under his arm. He was miserably poor. He had run away from Kumbakonam to get leisure in Madras to pursue his studies. He never craved for any distinction. He wanted leisure; in other words, simple food to be provided for him without exertion on his part, and that he should be allowed to dream on.

"He opened his note-book, and began to explain some of his discoveries. I saw quite at once that there was something out of the way, but my knowledge did not permit me to judge whether he talked sense or nonsense. Suspending judgment, I asked him to come over again, and he did. And then he had gauged my ignorance, and showed me some of his simpler results. I asked him what he wanted. He said he just wanted a pittance to live on so that he might pursue his researches. It is a matter of considerable pride to me that I was in some way useful to this remarkable genius in his earlier days."

Ramachandra Rao's interest took the most practical and generous form. He sent Ramanujan back to Madras so that he might work at the University there, and for a little more than a year he maintained him at his own expense. Many people, in India and in England, have been proud that they helped Ramanujan; of them all, perhaps his first benefactor deserves the highest praise.

---

* A talk broadcast in Hindustani in the Indian service on April 22, 1941.

Ramanujan, unwilling to be a burden for life, took in 1912 a clerkship under the Madras Port Trust, but Ramachandra Rao soon let the authorities of the Trust know what sort of a clerk they were employing, and thenceforward every assistance was given to Ramanujan. Francis Spring, the chairman of the Trust, made his post into a sinecure, and resolved to take the first opportunity of discussing the case with someone competent to appreciate Ramanujan's work. The opportunity came less than a year later, when an official visit was paid to Madras by Gilbert Walker, then director-general of observatories in India, a first-class mathematician trained in Cambridge. Walker's verdict, though he did not see Ramanujan and had only specimens of his work and not the note-books themselves to inspect, was unhesitating, and he wrote to the University authorities in Madras in the most emphatic terms: "The University would be justified in enabling S. Ramanujan for a few years at least to spend the whole of his time on mathematics, without any anxiety as to his livelihood." The words "at least" in this sentence are very remarkable. The University responded willingly, and with as little delay as was compatible with the fact that the situation was so far outside all precedent that explicit permission had to be secured from the Government of the Presidency, and on May 1, 1913, Srinivasa Ramanujan entered the Presidency College in Madras to practise as a virtue that single-minded devotion to mathematics which had been a vice in Kumbakonam nine years earlier.

Meanwhile, Ramanujan's name had become well known in Cambridge, the home of mathematics in England. G. H. Hardy, then a young lecturer at Trinity College and now the dominant figure among English mathematicians, who was destined to be closely associated with Ramanujan in the future, has sometimes said that Ramanujan was his discovery, but the truth is that Ramanujan chose Hardy. In a booklet dated 1910, Ramanujan found for the first time formulæ like some of his own, and acting on the advice of Seshu Aiyar, he wrote on January 16, 1913, a letter to the unknown author. No one who was in the mathematical circles in Cambridge at that time can forget the sensation caused by this letter. An obscure Indian clerk was appealing for advice because he was inexperienced, for help in the publication of his theorems because he was poor. "But only", he said, "if you are convinced that there is anything of value." Of the theorems sent without demonstrations, by this clerk of whom we had never heard, not one could have been set in the most advanced mathematical examination in the world. It must be confessed that the first suggestion was that the letter was a hoax, that the theorems must be familiar theorems skilfully disguised, but this explanation was soon abandoned, for there were some formulæ in the letter for which it certainly could not account. Of these Hardy has said, "They defeated me completely; I had never seen anything in the least like them before. A single look at them is enough to show that they could only be written down by a mathematician of the highest class. They must be true because, if they were not true, no one would have had the imagination to invent them." A great mathematician who has discovered formulæ of an entirely novel kind does not use them to mystify his friends.

Hardy answered the letter promptly, and Ramanujan knew that at last his intellectual solitude was at an end. His friends in India encouraged him and supported him, but none of them had the knowledge to bring him the human satisfaction of being understood and appreciated; to Hardy he wrote, "I have found a friend in you who views my labours sympathetically."

But if Ramanujan was contented because he had escaped drudgery and loneliness, in Cambridge it was clear that his genius was still in danger of being wasted. It is not that any brain could do mightier work anywhere than Ramanujan's had performed at Kumbakonam in the carefree days before 1909, but that mathematics is cumulative and inevitable. If the architect of the Taj Mahal had designed a different tomb for Arjumand Banu, the most beautiful building in the world to-day would not have come into existence. But if Euclid had not discovered that the number of prime numbers is infinite, nevertheless that same theorem would have been discovered long ago by somebody else. Moreover, the world of mathematics is no richer if somebody who has not heard of the theorem discovers it to-day for himself. Of Ramanujan's work before 1913, Hardy has written that it was inevitable that a very large part of it should prove on examination to have been anticipated. "He had been carrying", he says, "an impossible handicap, a poor and solitary Hindu pitting his brains against the accumulated wisdom of Europe." It is the accumulation in Europe that we have to emphasize; Ramanujan was beginning every investigation at the point from which the European mathematicians had started 150 years before him, and not at the point which they had reached in 1913. Close contact with mathematicians of the highest class was an urgent necessity for him, but he did not yet know this, and when Hardy asked if he would go to Cambridge, Ramanujan declined, reluctant to lose caste, and deferring to opposition on the part of his parents, whose objections were religious, and of some of his friends, who saw in this invitation a mean attempt to transfer to the English University the glory that belonged to Madras.

I visited Madras myself in the opening weeks of 1914. After my first lecture Ramanujan was introduced. We sat down, and he turned the pages of a note-book. Two days later he turned the pages again, and after our third meeting he said, "Perhaps you would like to take it away with you." The astounding compliment took away my breath. The priceless volume had never before been out of his hands: no Indian could understand it, no Englishman was to be trusted with it. The truth was, of course, that the English were objects of suspicion not as individuals but as components of the governing machine; I came from outside the machine, and, for no other reason than that, I enjoyed an overwhelming advantage which was grossly unfair. Richard Littlehailes, the professor of mathematics, in particular, had done and was to do far more for Ramanujan in Madras than I did.

Ramanujan's trust having been won so completely, I raised immediately the question of Cambridge, and found to my delight and surprise that Ramanujan needed no converting and that his parents' opposition had been withdrawn: in a vivid dream his mother had seen him surrounded by Europeans and heard the goddess Namagiri commanding her to stand no longer between her son and the fulfilment of his life's purpose. Lest he should be harassed presently by attempts to dissuade him, I addressed myself to the task of convincing his friends that the proposal was in Ramanujan's own interest. I wrote at once to

Hardy that the intangible obstacles had disappeared and that he must see that financial provision was made; I should try to obtain grants in Madras, but if I failed the money must somehow be found in England. I do not know what account I gave of Ramanujan and the note-books, but I made it abundantly clear that if Ramanujan was willing to come, financial difficulties simply must not be allowed to interfere. For a moment Hardy faltered. "Be careful what you promise", he wrote, and he forwarded a cautious memorandum of the "We-have-heard-of-these-untaught-geniuses-before" type, from the India Office in London. I claim no credit for ignoring this warning and laughing at Hardy's endorsement of it; I had seen the note-books and talked with Ramanujan, and Hardy had not. Moreover, while letters were travelling between Madras and London it was becoming likely that all the money wanted would be found in India. Littlehailes introduced me to everyone who carried weight in the University or in the civil administration; everywhere I talked of Ramanujan, explained as I have tried to do now the importance to him of a stay in Cambridge, and urged generosity. On January 28 I addressed to the University authorities a prophetic memorandum which began: "The discovery of the genius of S. Ramanujan of Madras promises to be the most interesting event of our time in the mathematical world", and ended: "I see no reason to doubt that his name will become one of the greatest in the history of mathematics, and the university and city of Madras will be proud to have assisted in his passage from obscurity to fame." Littlehailes drafted proposals in detail, and within a week the University, with the approval of the Government, had created a scholarship ample to maintain Ramanujan in Cambridge and his wife and mother in Kumbakonam. A few days later I left Madras.

It was in April 1914 that Ramanujan arrived in Cambridge, where he lived in my house until residential accommodation became available for him in July in Trinity. He felt the petty miseries of life in a strange civilization, the vegetables that were unpalatable because they were unfamiliar, the shoes that tormented feet that had been unconfined for twenty-six years, but he was a happy man, revelling in the mathematical society which he was entering, and idolized by the Indian students. The outbreak of war in the summer of that year affected profoundly his development. Most of the mathematicians whom it had been hoped that he would soon know disappeared from the University on war service of one kind or another; only Hardy remained, but Hardy had an unexpected amount of time at Ramanujan's disposal, and the two were constantly together. "I had to try to teach him", says Hardy, "and in a measure I succeeded, though obviously I learnt from him much more than he learnt from me." If Ramanujan's published papers are far narrower in scope than the note-books, if many of the ideas which had been born in India were neglected in England, it is because Hardy could guide Ramanujan rapidly and accompany him profitably only in regions of mathematics where he was himself at home. It was the War which separated Ramanujan from mathematicians with interests different from Hardy's but not alien to his own, and threw him into an association with Hardy so intimate that the two strands of their joint work cannot always be distinguished.

For three years, alone and in collaboration with Hardy, Ramanujan produced mathematical papers of the highest quality in rapid succession. Then he fell a victim to tuberculosis. Immediate return to India was impossible, for the war-time voyage was risky and uncomfortable. After a year's constant attention in English nursing-homes, his health showed some improvement, and he enjoyed a brief period of brilliant invention. It was at this time that the two highest academic honours in England, which had never previously been conferred on an Indian, were conferred on Ramanujan. Early in 1919 he returned to Madras: travel was again easy, and the purpose of his sojourn in Cambridge had been accomplished, his family and his friends were waiting for him, his native land was impatient to do him honour. To everyone's dismay, the voyage or the return to a warm climate caused a relapse; for a year every care was lavished on him, but he died in Madras on April 26, 1920.

During his last year he worked slowly and in pain, but the work showed the old invincible originality. His last letter to Hardy, dated January 12, 1920, is singularly reminiscent of the fateful first letter, for it, too, contained a multitude of formulæ with only the obscurest hints of the theory from which they were derived. He was developing his last theory until he died, and it is a measure of his genius that fifteen years elapsed before this theory was understood and made public.

I must not end without making an attempt to describe the man himself. In figure he was a little below medium height, and stout until emaciated by disease; he had a big head, with long black hair brushed sideways above a high forehead; his face was square, he was clean shaven, and his complexion, never really dark, grew paler during his life in England; his ears were small, his nose broad, and always his shining eyes were the conspicuous feature that Ramachandra Rao observed in 1910. He walked stiffly, with head erect and toes out-turned; if he was not talking as he walked, his arms were held clear of the body, with hands open and palms downwards. But when he talked, whether he was walking or standing, sitting or lying down, his slender fingers were for ever alive, as eloquent as his countenance. He had a fund of stories, and such was his enjoyment in telling them that in his great days his own irrepressible laughter often swallowed the climax of his narrative. He loved a paradox, but I do not know of any that he invented; the paradoxical element in some of his own early work must have made him aware that the wildest nonsense of to-day may receive a logical interpretation to-morrow. He had serious interests outside mathematics, and was always ready to discuss politics or philosophy. Loss of caste was a price he was prepared to pay for coming to England, but he kept the price as low as he could by adhering as closely as circumstances permitted to the observances of his religion, and in particular by maintaining the strictest vegetarianism. "When I go back", he said to me once, "I shall never be asked to a funeral", and if he spoke with a sigh there was no sense of pollution mingled with his regret. In everyday life he had an instinctive perfection of manners that made him a delightful guest or companion. Success and fame left his natural simplicity quite untouched. To his friends he was devoted beyond measure, and he devised curiously personal ways of showing his gratitude and expressing his affection. The wonderful mathematician was indeed a lovable man.

Had Ramanujan not left India he might be alive to-day, but he would have had always the sense of power and frustration, not of power and accomplishment. Death, too, was a frustration, but the life's purpose of which his mother dreamed was at least in part fulfilled, and it is better to be frustrated by unsought death than by life. So Srinivasa Ramanujan believed, for he told me just before he left England that he had never doubted that he did well to come.

DOMESTIC ENTOMOLOGY IN WAR-TIME

By DR. J. R. BUSVINE
London School of Hygiene and Tropical Medicine

IT is a curious paradox that the cyclopean evil and stupidity of a world war stimulate intelligent co-operation within smaller spheres. Anyone who has read the pages of NATURE during the present War will be aware that men of science are giving serious thought to their organization, status and general relations with society. Progress has certainly been made in the allocation of research problems, collaboration between individuals and application of results. Unfortunately, much of what has been done lies under a war-time ban of secrecy, but anyone who knows something of the work of the Biological War Committee (see NATURE of February 28, pp. 227 and 234) is aware that this is so. It must, however, be admitted that the symposium on "Domestic Entomology" held by the Association of Applied Biologists on February 20 revealed a lack of coordination of this particular type of problem. The pest species discussed were not linked on anatomical, physiological or even ecological grounds but rather from considerations of the organization of advice and control. Domestic pest problems are constantly confronting sanitary inspectors and medical officers who usually pass them on to one research institute or another. It would seem desirable that the Ministry of Health should retain an entomologist to deal with such specialized problems.

Interest in some domestic pests waxes and wanes with external events. Thus, research on lice and scabies is stimulated by war and to some extent lapses in peace-time. The drive on slum clearance a few years ago attracted attention to that perpetuator of slum life, the bed-bug. In addition to *ad hoc* research, a long-range ecological study of the bug was initiated, the results of which are only recently available[1].

A sound film on "Malaria", produced by the Shell Oil Co., was shown. This film was designed to be shown to non-technical people to give a clear picture of the causes and control of the disease without being dull or too complex. It not only succeeded brilliantly in this but also included pictures of great interest to the professional entomologist (particularly those of the female mosquito laying eggs and the realistic animated diagrams).

Dr. Busvine described some recent applied research which seems to provide a safeguard against epidemics of lice and the terrible diseases associated with them. While people are all able to get regular changes of undergarments, the body louse is not likely to spread rapidly, and occasional cases of infestation can be dealt with by improvements on methods used in the War of 1914–18. At any time, however, unhygienic conditions may arise as a result of severe bombing, invasion or other hazards of 'total' war which may favour the louse. If this pest becomes widespread it is exceedingly hard to eradicate, as was found in Flanders in the War of 1914–18 and in other subsequent epidemics. The difficulty, which consists in rapid reinfestation of deloused persons, can now be overcome by the use of lasting insecticides, applied in various ways, which 'proof' a person for a month after treatment. These methods, which have been thoroughly tested on verminous men, were illustrated by a short amateur film.

Dr. Busvine concluded by pointing out that the head louse, which is very much more common, is very closely allied to the body louse and may possibly be a disease vector. Similar lasting insecticides would be of value for this pest, applied as 'medicated' hair dressings.

The incidence of scabies in Great Britain is on the increase—a fact that cannot entirely be ascribed to war conditions because the increase started several years ago. Dr. K. Mellanby gave an account of some interesting recent research on the transmission of scabies. The experiments were made with the amicable collaboration of pacifist volunteers and scabetic soldiers.

Some controversy has arisen over the usual mode of transmission of the parasite; some holding that it is very largely indirect, others using that provoking word 'venereal'. It would be exceedingly difficult to discover what actually is the main mode of transmission, but Dr. Mellanby's experiments have certainly shown that indirect transmission is very much less efficient than even moderately intimate contact. Attempts to transmit the parasite on blankets or clothes were only successful one or two percentage of two or three hundred trials, whereas the mite was readily transferred between two men sleeping in the same bed, both wearing pyjamas.

Major Johnson reviewed the scabies problem from the statistical point of view. Although it is not possible to find all stages of the mite, the oviparous females can be counted with accuracy. Examination of scabetic cases revealed a remarkably low population compared with the numbers theoretically possible (estimating from the reproductive rate and length of the life cycle). Less than five live females were found on 50 per cent of the cases and only 5 per cent had more than sixty. Populations on individuals seldom rise sharply and sometimes decline to zero.

When we are living in the country we are often troubled by various families of biting flies. Dr. Kearns proposed thiocyanates as deterrents for our protection but warned us that what was effective for midges (Ceratopogoninæ) might be quite inefficient for 'clegs' (Tabanidæ). Some country houses are subject to periodic invasion by swarms of muscids and chloropids seeking to hibernate. They are very enterprising and persistent and it seems to be impossible to keep them out. The only remedy seems to be regular spraying by pyrethrum or thiocyanates in paraffin at the right time of year.

Dr. Kearns described a serious fly problem that has arisen in several bombed sites in our towns and cities. Wrecked food stores provided ideal breeding-grounds for houseflies and blowflies. Until it was possible to clear up the debris, a degree of control was achieved by weekly spraying with a tar oil emulsion and the use of an atomized spray for adults in neighbouring houses and shops.

Judging from inquiries at the Forest Products

Research Laboratory, furniture beetles are more prevalent than is often believed. Dr. Fisher pointed out that war-time furniture storage is likely to spread the trouble even further. Control of insects in wood is exceedingly difficult, but prevention of attack is much more feasible as a result of the researches on the physiology and dietetics of the pests. For example, it has been found that the so-called 'dry' wood-borer, Anobium, really needs a fairly high moisture content to flourish. Also the attack of Lyctus beetles can be prevented by elimination of starch.

Mr. Fox Wilson dealt with two pests less harmful but of considerable importance as nuisances. It is not generally realized that the invasion of houses by earwigs may actually render them uninhabitable. The reasons for such invading swarms are obscure, but they often occur on new building sites, and various connecting factors have been suggested.

The ants which trouble us in our houses and institutions may either be tropical species which have become 'domesticated' or invaders from the garden.

Both ants and earwigs can best be controlled by baiting, but whereas an arsenic-syrup bait is most effective against ants, the earwigs are most attracted by a bran-fluosilicate-fish-oil mixture.

---

OBITUARIES

Prof. Hans Spemann

The death of Hans Spemann, of Freiburg-im-Breisgau, at the end of 1941, brings to a close a life-time of work which threw a new and most revealing light on the great problem of the development of biological form.

Spemann was born in 1869. After leaving school he spent a few years in his father's business and in the performance of his military service, before beginning the study of medicine at the Universities of Heidelberg, Munich and Würzburg. He held his first position as a lecturer at the last-named University, passing from there to become professor of zoology at Rostock in 1908. During the War of 1914–18 he held a chair at the Kaiser Wilhelm Institute in Berlin, and in 1919 he was called to the professorship at Freiburg-im-Breisgau, which he held until his retirement in 1935, the year in which he was awarded a Nobel Prize for medicine.

Spemann's work did not cover a wide range of topics. His second paper, published in 1898, dealt with the development of the Amphibia; and this remained his field of investigation throughout his whole life. His great achievement was to bring into fruitful co-ordination the two, in themselves inconclusive, lines of attack which had been opened up in the casual investigation of development. On one hand, the studies of Roux and Driesch on the developmental potentialities of the first-formed blastomeres of the egg, although they tackled the major problems of the formation of the animal as a whole, seemed to lead only to a sterile paradox. On the other hand, Roux's notion of dependent differentiation appeared to suggest a plausible causal mechanism for development, but the one known example of it, and that a somewhat doubtful one, was concerned with the development of a single organ, the lens of the eye. Spemann entered both these fields, with his famous constriction experiments on the early cleavage stages of Triton, and his early grafting experiments on the optic rudiments of the same form. By 1918 he was able to bring forward his concept of the 'organization-centre', and demonstrate that the morphogenesis of the embryo, in its main outlines as well as in its details, is the result of interactions between different regions of tissue. For the next fourteen years, Spemann was the leader of a school, which rapidly filled in the outlines of what had come to be called 'embryonic induction'; their work was summarized in his Croonian Lecture of 1927. In 1932 he participated in the next major step forward, the beginning of the physico-chemical investigation of the process.

Although his work was one of the most important influences in the final discredit of vitalism, Spemann was never one of those who hoped that the discovery of the organizer would rapidly enable us to reduce the problem of biological form to a few simple chemical statements. His attitude was, in fact, much more a biological than a physico-chemical one. The extreme caution with which he formed his conclusions, joined with intense concentration on a narrow field favourable for an attack on fundamental problems, enabled him to lay a foundation on which the science of experimental morphogenesis can be securely based.

C. H. Waddington.

The Right Hon. Lord Salvesen, P.C., K.C.

Edward Theodore Salvesen brought to his profession and to his hobbies the vigour and enthusiasm bequeathed him by his Norwegian forebears. His profession carried him, by way of the University of Edinburgh, the Scots Bar and a sheriffdom, to a judgeship in the Court of Session of Scotland. His hobbies and his public interests were too many to mention, but he accomplished much for the veterans of the War of 1914–18 (in which his three sons were killed), he helped to reform the divorce law of Scotland, and he was a strong advocate of public-house reform. But his lasting memorial is the Scottish Zoological Park.

It was largely owing to his advocacy and to his energetic leadership as president of the Zoological Society of Scotland, founded in 1909 for the establishment of a national zoological park, the advancement of zoology, and the study of the native animals of Scotland, that the Park was opened in 1913. At that time it was a new venture in British zoos. The site of seventy-four acres with its mansion-house, gardens, fine trees and abundant natural exposures of rock invited broad and picturesque treatment, and the late Sir Patrick Geddes and Mr. F. C. Mears prepared the scheme for laying out the grounds.

Developments, carried out step by step under Lord Salvesen's guidance, as the funds of the Society warranted, have resulted in a park of great attraction, with spacious paddocks, and rocky dens in which the animals live and are seen to the best advantage.

Lord Salvesen presented to the Society its acclimatization house adapted for some less hardy creatures, and was instrumental in obtaining from the Carnegie Trustees the grant which built the Carnegie Aquarium. His and his brother's connexion with the whaling industry in South Georgia enabled them to bring together in the Park what must have been a unique collection of penguins in captivity. For at its best the collection comprised twenty-eight king penguins, which regularly bred and reared young, in addition to the ringed, gentu, rock-hopper and black-footed species. The War, alas, has destroyed some of the glory of that interesting group, as it has interfered with many of the accustomed inhabitants of the Park; but Lord Salvesen's experiment in planning a modern zoological garden has been abundantly justified and will continue for long to give to its many visitors pleasure mingled with instruction.

After a short period of ill-health Lord Salvesen died on February 23, still a man of vigour, in his eighty-fifth year.

JAMES RITCHIE.

WE regret to announce the following deaths:

Sir Henry Brackenbury, vice-president of the British Medical Association and, during 1927–34, chairman of the Council, on March 8.

Dr. H. D. Curtis, head of the Department of Astronomy and director of the Observatory, University of Michigan, on January 8, aged sixty-nine.

Prof. H. W. Foote, professor of physical chemistry in Yale University, on January 14, aged sixty-six.

Mr. P. G. Redington, forest supervisor of the U.S. Forest Service, formerly chief of the U.S. Biological Survey, on January 12, aged sixty-three.

Mr. F. J. Selby, C.B.E., secretary of the National Physical Laboratory during 1918–32, on March 5, aged seventy-four.

NEWS and VIEWS

The Poulkovo Observatory

INFORMATION that the Poulkovo Observatory had been severely damaged in the German bombardment of Leningrad was first received in a special message to the men of science of Great Britain broadcast from the besieged city on October 8, 1941, by Prof. Vassily Ogorodnikov, professor of physics in the University of Leningrad, who was fighting in the ranks of the Red Army defending Leningrad. The Observatory lies some twelve miles south of Leningrad, not far from the railway line from the German frontier to that city. The shelling of the Observatory appears to have been deliberate, and from later information it is learnt that its destruction is practically complete.

The Poulkovo Observatory was founded in 1839 by the Emperor Nicholas and recently celebrated its centenary. The first director was F. G. W. Struve (1793–1864), who had been the director of the Dorpat Observatory during 1818–1839. He was commanded by the Emperor to design and erect, almost regardless of cost, the most perfect and complete observatory that he could devise. Struve had a zeal for refined and precise methods of observation and, in addition, an inventive mechanical and engineering capacity, and he took full advantage of this unique opportunity. His "Description de l'Observatoire Astronomique Central de Pulkowa" is a work which, in the words of Sir David Gill, "no one, even in the present day, who may be charged with the design and erection of a great observatory, can afford to neglect". From the time of its foundation, the Poulkovo Observatory has taken a leading part in fundamental astronomy, for which its high latitude particularly fitted it. The standard refraction tables used in the reduction of astronomical observations are the Poulkovo refractions, based on Poulkovo observations. The fundamental observations made there have always been planned with care and characterized by their high accuracy, so that in the formation of a fundamental system of star places the Poulkovo catalogues receive very high weight.

The instrumental equipment of the Observatory included a Repsold meridian circle, an Ertel-Merz vertical circle, a Repsold prime-meridian transit instrument, a Repsold-Clark 30-in. refractor of 46 ft. focus, a Repsold-Merz 15-in. refractor of 27 ft. focus, in addition to numerous smaller instruments. F. G. W. Struve retired in 1861 and was succeeded as director by his son, O. W. Struve (1819–1905), who retired in 1889. The two Struves between them practically laid the foundations of double-star astronomy, by their discoveries and observations of double stars. J. O. Backlund (1846–1916), who was director during 1895–1916, made important investigations on Encke's Comet, the period of which (about 3·3 years) shortened by 2½ days between 1819 and 1914. In a memoir that is a classic, he showed that the motion of the comet is retarded in a narrow region not far from perihelion by a resistance of some sort, and that this resistance has decreased rather abruptly several times. The library of the Poulkovo Observatory was one of the most complete astronomical libraries in existence, and its treasures included many of the manuscripts of Kepler. It is hoped that steps had been taken before the German attack to remove the valuable books and manuscripts to a place of safety. The Poulkovo Observatory was an institution of which the Russians were justly proud, and men of science in all countries will share with them their grief at its destruction.

Scientific Co-operation between Great Britain and the U.S.S.R.

THE Parliamentary Secretary of the Ministry of Information (Mr. Ernest Thurtle, M.P.) opened a conference of British scientific and technical institutes on March 9 at which Sir John Russell, adviser to the Soviet Relations Branch of the Ministry of Information, took the chair. The conference, which took place in the rooms of the Royal Society, was called to discuss an intensification of the exchange of technical and scientific information between the U.S.S.R. and Great Britain. Some sixty scientific organizations and learned societies of Great Britain sent representatives to the conference, and it was decided to set up a standing committee to assist the Ministry of Information in this work and to act as a clearing-house between organizations in Great Britain and their opposite numbers in the U.S.S.R. A representative of the Soviet Government is to be invited to join the subcommittee.

Government Plans for Reconstruction

WITH the completion of the recent Cabinet changes, it is announced that Sir William Jowitt, who was Solicitor-General, has been appointed Paymaster-General, in succession to Lord Hankey. The duties hitherto performed by the Minister without Portfolio in connexion with the study of post-war reconstruction problems will in future be carried out by the Paymaster-General, who has been charged with general responsibility for organizing and co-ordinating the work on reconstruction problems now being carried out by the various Departments of State. For this purpose he will have at his disposal the special section which has been engaged on this work under the Minister without Portfolio. Arrangements will continue whereby reconstruction questions are considered by a committee of Ministers containing representatives of the political parties. Mr. H. G. Strauss, M.P., has been appointed an additional Parliamentary Secretary at the Ministry of Works and Buildings. In this office, Mr. Strauss will be responsible under the Minister for the planning functions of the Ministry.

The general responsibility hitherto entrusted to the Minister without Portfolio in regard to export surpluses and allied post-war relief will in future be exercised by the President of the Board of Trade. It is also officially announced that Sir Frederick Leith-Ross, chief economic adviser to the Government, will continue to direct the organization concerned with export surpluses and allied post-war relief, which will now be attached to the Board of Trade instead of to the Ministry of Economic Warfare, and he will relinquish his post as Director-General of the Ministry of Economic Warfare.

Scientific Invention at the Service of the Community

MR. P. H. B. LYON, headmaster of Rugby School, was in the chair when Capt. John Langdon-Davies addressed the Rugby branch of the Association of Scientific Workers on March 5 on "Scientific Invention at the Service of the Community". After referring to Prof. J. D. Bernal's book on "The Social Function of Science" as giving a detailed picture of the organization of science and the imperfections consequent upon a system of production for profit, Capt. Langdon-Davies passed on to a consideration of the effects of social phenomena that influence education more than do schools and universities, such as advertising, with its creation of false appetites for 'streamlined' refrigerators. The need is for social planning, including a planned attack by men of science on the most urgent problems, not only of war but also of peace. Capt. Langdon-Davies looks to the development of substitutes for raw materials such as rubber, as a means of wiping out the pools of semi-slave cheap native labour which he regards as one of the prime causes of imperialistic conflict. Only by raising the standards of life of the peoples of Asia and Africa, he contended, can we hope for permanent social security. He pointed out that science exercises an influence on spiritual values, suggesting that the moral theology of the medieval Schoolmen was not unscientific but based on the incorrect science of Aristotelean physiology. He called for a "sense of reverence" from scientific workers. In conclusion, he insisted that scientific method must be applied to politics and economics, demanding, however, that we must preserve our criteria and standards of scientific truth in politics.

Centenary of General Shrapnell

ON March 13, 1842, Lieut.-General Henry Shrapnell, the distinguished artillerist and inventor, died at his home, Peartree House, Southampton, at the age of eighty, having spent his whole career in the improvement of guns and projectiles. Born at Bradford-on-Avon on June 3, 1761, he entered the Royal Artillery at the age of eighteen and continued to serve until 1825, when he was retired with the rank of major-general. In 1837 he was promoted lieutenant-general. Fused hollow shells had been used since the time of Vauban, but Shrapnell was the first to introduce shells filled with musket bullets and with a bursting charge for firing from long guns. His first demonstration was made at Gibraltar in 1788, but it was not until 1803 that Shrapnell shells were adopted by the Board of Ordnance. In that year Shrapnell carried out a large number of firing experiments at the works of the Carron Company, Falkirk, and the company was given orders for large numbers of this new projectile. Shrapnell shells were used at the Siege of Surinam in 1803, in the Peninsular War and at the Battle of Waterloo. The inventor spent many thousands of pounds of his own money on the experiments; he was given a pension of £1,200 in 1814. At his death Shrapnell was buried in the family vault in the parish church of Bradford-on-Avon, where a tablet erroneously gives the year of his death as 1847.

Uses of Colloidal Graphite Solutions

THE general scarcity of metals lends a special interest to the use of dispersions of colloidal graphite in water for making non-metallic bodies electrically conducting. On glass or similar substances which can be thoroughly cleaned with chromic acid, the graphite dispersion can be applied with a soft brush. Glass elbows and intricately shaped parts of evacuated systems can, by this method, be fitted with conducting shielding. Absorbent surfaces such as wood veneer or rubber tubing are best saturated to a slight depth below the surface with a dilute solution and then coated with the more concentrated form. It is suggested that by this means cabinets or even whole research rooms can be electrically shielded by applying the liquid by brush-painting or air-spraying followed by air-drying. Soft-cloth polishing, by forcing the particles into closer contact, automatically increases electrical conductivity. Leads for connexions or for earthing the screens are sealed into the glass or are fitted externally before applying the liquid. In Great Britain the product is sold as 'Aquadag' by Messrs. E. G. Acheson, of 9 Gayfere Street, London, S.W.1. Details were published in 1936 by B. H. Porter in NATURE, 137, 1034, and in the *Review of Scientific Instruments*, 7, 101.

The Hannah Dairy Research Institute

THE activities of the Hannah Dairy Research Institute, Kirkhill, Ayr, described in its twelfth annual report, are, as would be expected, chiefly concerned with the maintenance of the country's milk supply. The problem is approached from two main aspects, namely, the biological and the technical. Under the former category come investigations as to the provision of adequate home-grown feeding-stuffs and the avoidance of disease in the herd. Grass silage has been successfully produced in large quantities on the Institute's farm; but dried grass, though a first-class product from the feeding point of view, is regarded as probably not economic for the moderate-sized dairy farm. The possibility of improving the protein ration by feeding non-protein nitrogen compounds such as urea, with the idea that it would be converted into protein in the rumen of the animal, is under investigation. No far-reaching results are yet announced, but when roughly one third of the protein of the production ration was supplied in this form, the health, milk yields and body weights of the cows remained unimpaired during the six-week trial period. As regards disease prevention, control measures against mastitis have been extended, and the use of sulphanilamide administered orally has met with marked success. Dried milk products are being studied on the technical side, factors affecting their solubility and keeping quality receiving special attention. It appears that the addition of antioxidants to the precondensed milk before drying considerably increases the keeping quality of the resultant powder.

Earthquake at Santa Barbara, California

FROM *Earthquake Notes* of December, 1941, we learn that a severe earthquake occurred at Santa Barbara, California, at 11.51 p.m. P.S.T. on June 30, 1941. This was followed by a swarm of after-shocks which continued for several days. Shocks of any consequence ceased to occur at about noon on July 3, but three shocks were reported on this date. A preliminary report from the seismological laboratory at Pasadena gives the epicentre location as 34° 20′ N., 119° 35′ W. This position is about eight miles off shore in a south-easterly direction from Santa Barbara. Damage was estimated at about 150,000 dollars. Maximum intensity was about VII or VIII on the modified Mercalli scale. Accelerograph records of this shock were obtained at Santa Barbara, Long Beach and Vernon. The record obtained at Santa Barbara is being analysed by integration methods and the results are expected later.

"Davitamon-Five" Vitamin Tablets

MESSRS. ORGANON LABORATORIES, LTD., Brettenham House, Lancaster Place, London, W.C.2, have recently put on the market a new preparation of vitamin tablets named "Davitamon-Five". This preparation is intended for those people who wish to ensure that they are ingesting an adequate quantity of essential vitamins. The tablets are intended for the day-to-day prophylaxis and treatment of mild hypovitaminoses; and since a number of research workers have made it clear that specific avitaminotic symptoms are abolished more rapidly when the diet is adequate in the other vitamins, they can also be used to provide a suitable background for an intensive single-vitamin therapy. Each tablet contains: 1,000 I.U. vitamin A; 50 I.U. vitamin B_1; 200 I.U. vitamin C; 200 I.U. vitamin D; 0·5 mgm. *PP* factor of the B complex. A sample of the tablets can be obtained from the above laboratories.

Science Masters' Association: Annual Meeting

THE forty-first annual meeting of the Science Masters' Association will be held at Rugby School during April 8–10, under the presidency of Mr. P. H. B. Lyon, headmaster of Rugby School. The subject of the presidential address will be "English in the Science Course". Lectures will be delivered by Prof. M. L. E. Oliphant on "Recent Practical Applications of Nuclear Physics" and by Mr. L. J. F. Brimble on "Human Biology in Education". Prof. L. T. Hogben will deliver the Science and Citizenship Lecture. A discussion on "Science in Post-war Education" will be opened by Mr. E. G. Savage. Further information can be obtained from Mr. W. Askhurst, Grammar School, Stretford, Lancs.

Announcements

PROF. A. W. M. ELLIS, professor of medicine, University of London, has been appointed director of research in industrial medicine by the Medical Research Council.

SIR EDWARD APPLETON, secretary of the Department of Scientific and Industrial Research, will deliver the twenty-sixth Guthrie Lecture of the Physical Society on March 20. He will speak on "Ionospheric Influences on Geomagnetism".

MR. W. T. HALCROW will deliver the thirty-second May Lecture of the Institute of Metals on May 31 at the Institution of Mechanical Engineers. The title of the Lecture will be "Water Power and its Application to the Production of Metals".

MR. S. BAIRSTOW, of the Chemical Research Section, Research Department, of the London Midland and Scottish Railway, has been awarded the Herbert Jackson Prize for 1941, for a paper entitled "The Relation between Calorific Value and the Road Performance of Producer-Gas Vehicles".

AT the request of the Minister of Agriculture, the National Institute of Agricultural Botany has set up a special Seed Production Committee the duty of which will be to take all possible steps to stimulate, co-ordinate and ensure home seed production. The chairman of the Committee is Mr. W. Gavin, agricultural adviser to the Ministry of Agriculture. The executive officer is Mr. Leslie E. Cook, and all communications should be addressed to him at the National Institute of Agricultural Botany, Huntingdon Road, Cambridge.

A COPY of the third (revised) edition of a pamphlet on "The Colorimetric Determination of Oxidation-Reduction Balance" has been received from the British Drug Houses, Ltd., Graham Street, London, N.1. This gives in simple language a summary of the theory of oxidation-reduction processes and potentials, and of oxidation-reduction indicators and their uses in volumetric analysis and in several fields of work, including biochemistry and soil chemistry. Copies of this useful pamphlet can be obtained free of charge on application to the British Drug Houses, Ltd.

THE Lady Tata Memorial Trust is prepared to consider applications from workers in Great Britain for grants or scholarships for the year beginning October 1, 1942, for research on blood diseases, with special reference to leukæmia. Under present conditions it is not possible to deal with new applications from workers overseas. Inquiries must be addressed to the Secretary, Scientific Advisory Committee, Lady Tata Memorial Trust, c/o London School of Hygiene, Keppel Street, London, W.C.1, not later than March 31.

Excretion of Ketosteroids in Human Pregnancy Urine in Relation to the Sex of the Fœtus

It has long been known that when a cow gives birth to calves, one a male and the other a female, the male will grow into a normal bull while the female may be a freemartin. The freemartin is zygotically a female and the external genitalia and mammary glands, though modified, are usually of female type, but the gonads histologically resemble testes rather than ovaries and there is a tendency for the Wolffian ducts to persist whereas the oviducts are absent or incomplete. Fusion of the placentæ with anastomosis of their blood vessels is an essential factor in producing the freemartin. Because of the common blood supply the testicular hormones of the male have free access to the female twin and cause her reproductive organs including her gonads to conform towards the male type. Parabiosis experiments in animals and also histological examination of embryonic gonads in several species seem to show that in embryos the androgenic cells of the male gonad begin to secrete before the ovary has become completely differentiated, and that the ovary does not produce secretion until a much later stage of development. It seems also that the androgens produced in early embryonic life are abundant enough to cause profound and permanent changes in the ovaries of a female twin.

These considerations suggested that it might be of interest to examine the urine of women in the early stages of gestation to discover whether the testes of a male embryo might produce enough androgen to cause a recognizable increase of androgen in the mother's urine. The most likely time for a positive result in such a test would be in early pregnancy, since involution of androgenic tissue in late pregnancy has been observed in some species.

Samples of pregnancy urine were obtained from twenty women and the ketosteroids estimated colorimetrically. Collection of complete 24-hour specimens proved impracticable and the estimations were carried out on samples of morning urine. All urines were collected 8–12 weeks after the last menstrual period. It was afterwards determined that fourteen women were bearing a male fœtus; their average ketosteroid excretion was 26·2 mgm. per litre. The six women bearing female fœtuses had an average excretion of 14·6 mgm. per litre. When account is taken of the wide range of the individual values in these two series, it is apparent that the difference between the mean excretions is not significant ($t = 1{\cdot}8$). The highest value observed in a female pregnancy was 19·8 mgm. Seven of the male pregnancy values exceeded 20 mgm., the highest value being 80 mgm. per litre. Assays carried out at later stages of the pregnancies showed that initially high ketosteroid contents tended to fall whereas moderate assays remained substantially unchanged.

Details of these experiments will be published elsewhere. We are unable to continue this work at the moment and the purpose of this note is to suggest that it would be interesting to examine a larger series. We realize fully the limitations imposed by the smallness of the present series, but the facts that (*a*) the seven very high values reported above all occurred in male pregnancies, and that (*b*) in the later stages of pregnancy these values tended to fall to the general average for all the cases, are in agreement with the hypothesis that the source of the extra excretion lies in the gonad of the fœtus. The possibility that the fœtal adrenal cortex plays some part cannot, of course, be excluded.

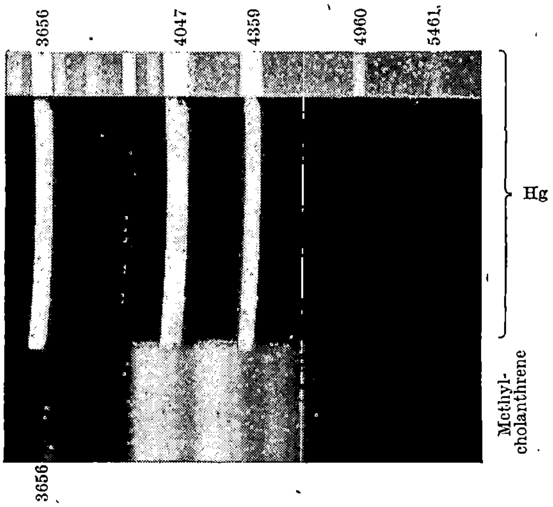
Fluorescence of Methylcholanthrene

The letter on "Fluorescent Lipoidal Spectra of Human Tissue" in NATURE of February 14, p. 193, requires comment upon several points.

Dr. Penn's statement that I reported . . . "that most of the carcinogenic hydrocarbons studied were highly fluorescent and they produced characteristic bands in the regions 4000, 4180 and 4400 A" . . . is, I regret to point out, incorrect. The regions of the spectrum quoted referred to the bands shown by the carcinogenic tars and tar fractions, and by the complex carcinogenic mixture prepared from tetralin by Prof. Kennaway. Further work has only emphasized that the various carcinogenic hydrocarbons have different fluorescence spectra and that there is sufficient correlation between their chemical structure and spectra to make identification by this means a very useful experimental aid. Thus 1 : 2 : 5 : 6-dibenzanthracene and the "1 : 2 : 7 : 8-dibenzanthracene" prepared by E. Clar certainly gave the same fluorescence spectrum, but Prof. Cook proved that the compound which Clar thought to be 1 : 2 : 7 : 8- was really 1 : 2 : 5 : 6-dibenzanthracene. When Cook did synthesize 1 : 2 : 7 : 8-dibenzanthracene, its spectrum was found to be completely different from that of the 1 : 2 : 5 : 6- isomer.



HG SPECTRUM AND FLUORESCENCE SPECTRUM OF METHYLCHOLANTHRENE.

Dr. Penn finds that cancer tissue lipoids produce a far stronger fluorescence than do the lipoids of non-cancer tissue, and that the spectra are different. The number of specimens which have shown these differences is not stated. Such a result would be most agreeable, but here we have so far failed to show any differences in fluorescence between fatty extracts of cancer and non-cancer tissues. I have not used the method of extraction which Dr. Penn considers to yield a solution of "lipo-protein" in acetone. However, this subject is still under investigation.

Dr. Penn's fluorescence spectrum of methylcholanthrene suggests that he has been the victim of an unfortunate mistake. A sample made from deoxycholic acid by Prof. Cook in 1933 and a synthetic sample made in 1938 give very much the same fluorescence spectra : three massive bands extending over about 800 units of wave-length, the well-marked mercury line 4047 lying near the interval between the first and second bands (see figure). This hydrocarbon fluoresces very powerfully in the most sensitive region (violet) of the photo-sensitivity curve of an ordinary plate, and a concentration of 1 in 400,000 is quite enough to give a strong negative in the spectrograph.

Biotin as a Possible Growth Factor for Insects

IT has been shown for several insects, namely, Lucilia[1], Drosophila[2] and Tribolium[3], that the larva requires a growth factor which is contained in the water-insoluble fraction of yeast and is not fat-soluble. This can be easily demonstrated with *Tribolium confusum.* This beetle, which normally breeds on wholemeal flour, grows almost equally well on a diet consisting of casein, glucose, yeast, cholesterol, salts and water added to make a water content of about 15 per cent. If a water-soluble yeast extract (prepared according to Chick and Roscoe[4]) is supplied instead of yeast, growth is very much retarded (1) (see accompanying table), but normal growth is restored by adding the water-insoluble fraction of yeast (2). The same result has been obtained with the following three species of beetles which are all common pests on stored food : *Sitodrepa panicea, Lasioderma serricorne* and *Silvanus surinamensis.* The need for an 'insoluble' factor in yeast seems, therefore, to be of general occurrence in insects. This factor is not fat-soluble, because the adding of a chloroform-soluble extract of yeast (3) or of wheat germ oil (4) only very slightly improves diet (1). It is not considered to be entirely absent from yeast extract because in that case development would presumably be impossible. This view is supported by the fact that tripling the amount of yeast extract improves the diet considerably (5). A water-soluble liver extract shows about the same deficiency (6) as the corresponding yeast extract (1). The filtrate of autoclaved yeast improves diet (1) and so does marmite (7) (which is virtually an autolysed yeast extract).

BASAL DIET: 50 parts casein, 50 parts glucose, 1 part cholesterol, 1 part McCollum's salt mixture and 15 parts yeast extract.
20 larvæ in each test.
Temperature 25° C., relative humidity 70 per cent.

Additions to basal diet		Period in days during which first 10 pupæ were formed
(1)	None	45–53
(2)	Insoluble yeast	26–31
(3)	Chloroform extract of yeast	40–46
(4)	Wheat germ oil	40–44
(5)	Three times quantity of yeast extract	34–41
(6)	None, but liver extract instead of yeast extract	43–56
(7)	Marmite	32–36
(8)	Lecithin	40–45
(9)	Vitamin-H concentrate from yeast ...	34–40
(10)	Biotin-concentrate from yolk	29–34
(11)	None, but starch instead of glucose ...	30–33

These and other properties of the insoluble factor suggest a similarity to György's vitamin H which has recently been shown to be identical with biotin and been recognized as an essential food factor for the rat[5]. Kögl[6] has shown that commercial lecithin always contains traces of biotin and, in fact, diet (1) is slightly improved by the addition of lecithin (8). György[7] prepared a vitamin-H concentrate from the water-insoluble residue of liver by autoclaving and treating the resultant solution in turn with acetone and with alcohol. The same treatment applied to the insoluble fraction of yeast yielded an extract which, when added to diet (1), improved it very considerably (9). Kögl's[6] original isolation of biotin from yolk was started by boiling in water and removing in turn all that precipitates with acetone and alcohol. The same treatment applied to the yolk of one egg yielded a solution which when added to diet (1) improved it almost to the efficiency of diet (2) which contained the insoluble fraction of yeast (10).

These results make it very likely that the 'insoluble' factor in question is in fact biotin. The final proof must, of course, wait until a test can be performed with pure biotin in place of insoluble yeast fraction. Although biotin has recently become available in the United States, we have so far not been able to procure a sample and have to postpone this experimentum crucis until it arrives.

It is noteworthy that a 'biotin' deficiency cannot be demonstrated with Tribolium when the carbohydrate in the diet is starch instead of glucose (11). This suggests that the purest samples of starch which are available contain sufficient traces of biotin, and presumably explains why a biotin deficiency of rats has hitherto only been demonstrated as the so-called egg-white injury (that is, in a diet which contains large amounts of egg-white). It has often been stated that rats can be grown well on a diet in which the vitamins of the B-group are supplied in a water-soluble yeast extract. Such diets should be, on paper, deficient in biotin. It may be suggested that this deficiency is usually made good by traces of biotin in starch which is almost invariably the carbohydrate used in dietary experiments. In fact, it has recently been shown that diets in which starch is replaced by sucrose are apt to give inferior results[8,9].

A Photographic Method of Estimating the Mass of the Mesotron

WE have described[1] a method of estimating the mass of secondary particles with heavy ionization tracks in photographic emulsion which are due to some component of the cosmic ray. The method is based upon the determination of the kinetic energies of these particles and of protons with the same initial velocities, which according to our assumption produce tracks with the same mean grain spacings in the emulsion.

The method used requires to be amended in two ways:

(1) In the application of Williams's formula for scattering[2], which can be written as $\overline{\theta} = A . \frac{Ze^2}{W}\sqrt{Nt}$ in a medium with atoms of one kind, Z is the nuclear charge and N the number of atoms per unit volume. For the photographic emulsion, we have to sum up for the scattering due to the different kinds of atom with different values of Z. For this purpose we used a mean value of Z defined as $\overline{Z}.N = \overset{n}{\underset{1}{\Sigma}} Z_k N_k$. Since the value of $\overline{\theta}$ is deduced from that of $\overline{\theta^2}$ which is defined as $\frac{2}{\pi}$ times the mean square of θ, the value of Z to be used in our formula is the root mean square of Z, namely, $\overline{Z^2}.N = \overset{k}{\underset{1}{\Sigma}} Z_k{}^2 N_k$. While $\overline{Z}$ is 6·2, $\sqrt{\overline{\overline{Z}^2}}$ is 11·3. This was pointed out to us by Dr. H. J. Bhabha in a private communication, for which our thanks are due to him.

(2) The second correction refers to the way the lengths of the ionization tracks in the emulsion were grouped together in the table given in our previous communication. There was a certain arbitrariness in our method of grouping, which while giving a series of more or less concordant values of the mesotron mass, is not sufficiently randomized. In the present calculation all the tracks are grouped together for which the mean grain spacings lie within definite ranges of 6–5, 5–4, 4–3, 3–2 μ. Further, we have used three more photographic plates exposed to neutron radiation from a radium-beryllium source to obtain a more accurate calibration curve for proton tracks.

The recalculated values of the mesotron mass are given in the accompanying table, for which A has been taken to be 3·69. If the more accurate formula (40) of Williams is taken, in which a correction for the finite nuclear radius is introduced, the value of A becomes 4·14, which raises the value of μ by 12 per cent.

Mean grain spacing 10^{-4} cm.		6–5	5–4	4–3	3–2	Mean value
Value of mesotron mass μ in units of m_0	Plate A	221	160	236	(1723)	217 ± 30
	B		316	355		336 ± 19·5
	C	278	318	342	(1743)	313 ± 18·6

Plate A was kept under air, and B under 20 cm. of water at Sandakphu, and plate C at Phari Jong, Tibet, in the Post Office building under a roof thickness of 2½ ft. of mud and wood. The consistently high values of mesotron masses found with plates B and C are probably due to the presence of proton tracks in these plates, due to collision of primary neutrons with hydrogenous matter. This is further evidence of the paucity of fast primary protons in comparison to the number of similar neutrons in the cosmic ray. In all the plates for mean grain spacing 3–2 μ, the tracks are largely due to protons; in this region the proton calibration curve is not accurate.

We have also determined the mass of the mesotron from the curvatures of the pair tracks in the emulsion; the value is found to be 186·0 m_0. Owing to the shortness of range in the emulsion of most of the star-tracks, similar determinations have not been possible with such tracks.

It is to be noted that in the calculations with Williams's formula we have used individual values of θ, rather than its mean value; this is conditioned by the nature of our investigation. The values of μ so obtained will be distributed statistically about the true value; the mean value of μ obtained for the set of observations with plate A will approximate closer to the true value than any of the individual ones.

As stated in our previous communications, the importance of these results lies in the support they give to the view that multiple mesotron production in a single act by some component of the cosmic ray is possible, the principal contributor being, according to our results, the neutron. This is in accordance with the views of Heisenberg. Further interest has been directed to this process by the recent investigations carried out in the United States, which have led to an attempt by Carlson and Schein[3] to explain the totality of the cosmic ray processes taking place in the earth's atmosphere as being due to the impact of a single primary particle, the proton. According to their views, the initial step consists in the creation in one explosive act of a large number of mesotrons, in which the primary proton by interaction with a nuclear particle in the upper atmosphere loses all its energy. So far as the creation of mesotrons is concerned, protons and neutrons are about equally effective. Our results appear then as an experimental support of Carlson and Schein's assumption. The further question then arises whether the fast neutrons which are found in the earth's atmosphere are entirely of secondary origin.

Self-incompatibility in Polyploid Forms of Brassica and Raphanus

IN a recent paper Lewis and Modlibowska[1] have suggested that in autotetraploid pears pollen of the constitution S_1S_2 is capable of functioning in $S_1S_1S_2S_2$ styles—thus a self-incompatible diploid of the constitution S_1S_2 will produce by somatic doubling a self-compatible autotetraploid $S_1S_1S_2S_2$. In colchicine experiments I have observed many times that no such change occurs in *Brassica Rapa*, *B.*

campestris and *Raphanus sativus*—in these three species the autotetraploid and the diploid branches of colchicine-produced diploid-tetraploid sectorial chimeras have always both been self-incompatible. It was also possible in these cases to show that one was dealing with normal self-incompatibility and not with some disturbance produced by the colchicine treatment, since seeds could be obtained from both the diploid and autotetraploid branches by either bud pollination or the stigma-shaving method of Sears[2]. Lewis has also found that autotetraploid branches of *Œnothera organensis* are self-incompatible like the diploid.

The above Brassica results do not in any way invalidate Lewis and Modlibowska's suggestion that in pears S_1S_2 pollen can grow down $S_1S_1S_2S_2$ styles, since the mechanism of self-incompatibility in Brassica is different from that in pears. In Brassica, as is shown by the stigma-shaving method, self-incompatibility is due to the outer layers of the stigma while in pears it is due to the slow growth of pollen-tubes inside the style.

Brassica chinensis autotetraploids behave in the same way as those of *B. campestris* except that *B. chinensis* shows cyclic compatibility[3]. In *B. oleracea* both self-compatible and self-incompatible plants occur in the diploid[4] and both types have also been found in the autotetraploids.

It would also be interesting to know whether amphidiploids from a cross between two self-incompatible diploid Brassica species would be self-compatible since the three allotetraploid species, *B. Napus*, *B. carinata* and *B. juncea*, are self-compatible. The following two results suggest that they might be self-compatible. No self-incompatible plants have been found in the Cambridge *Raphanus sativus* × *Brassica oleracea* amphidiploids although these plants have been selfed for three generations[5,6]. It is not, however, known whether the two original parents were self-incompatible, but on the other hand, Kakizaki[4] was unable to obtain *Brassica oleracea* plants which would breed true for self-compatibility. Also amphidiploids from the cross self-incompatible *B. chinensis* × self-compatible *B. carinata* are self-compatible[7].

Search for Petroleum in Australia

MY attention has been directed by Mr. Frederick Chapman to Mr. H. B. Milner's review which appeared in NATURE of January 4, 1941, p. 13. Certain aspects of the Lakes Entrance field were obviously not available to Mr. Milner at the time. His reference to emulsified oil is now known to have no relevance—natural unemulsified oil exists throughout the glauconite (the reservoir rock); when this oil is baled or where it has risen to or near the surface, there is no emulsion. The emulsion only occurs where water has been allowed to enter the wells and when pumping is resorted to. Under those conditions, due to the churning action of the pump used, an oil-in-water emulsion occurs.

Then again, Mr. Milner, in quoting from Government reports, says the trouble with Lakes Entrance is that there is no natural pressure to cause oil to flow in the wells when the sands are penetrated. Actually (*vide* Ranney-Fairbank report on tests of Imray Well made in the presence of Dr. Raggatt, geological adviser, Commonwealth Government, and State Mines Departmental officers), the position is as follows:

"However, in the Imray Well, which was drilled only 21 feet into the glauconite, the fluid has been rising for 695 days; the rate of rise at first was 5 feet (5·4 gallons) per day, total height of the column in the hole was 1,164 feet and the top of the column stood at 110 feet from the surface. The column was still rising on July 13th this year. The fluid column consisted of 173 feet of water and 991 feet of oil (1,100 gallons by measurement in tanks). It appears, therefore, that the fluid produced was approximately 85 per cent oil. Because of the fact that the fluid rose in the well to the height attained and would undoubtedly have risen, in time, to about 100 feet above sea level, it is indicated that instead of being termed a 'low pressure' field, Lakes Entrance might more properly be called a low permeability field. From these observations it is indicated that there is a possibility that the hydrostatic head existing below the oil sand can be turned to advantage in proper operation of horizontal wells into a natural water drive, to flush the oil into the wells."

The summarized information in the Ranney-Fairbank report furnished to the Commonwealth Government is that the oil content of these sands at Lakes Entrance is approximately 400 barrels per acre foot, or 11,600 barrels per acre; a 25 per cent recovery at least is expected.

Messrs. Avery and Anderson, in a review of information gained from Victorian Mines Department reports, show that 1 per cent by weight oil content of the glauconite would provide 4·55 gallons per cubic yard.

The summarized position is that recent carefully checked information has enabled a better knowledge and application of the field to be gained, Sir Edmund Teale's views, appearing in the same issue of NATURE (p. 31) being strongly supported by these later investigations.

Melbourne, C.1.
Oct. 21, 1941.

WHILE it is gratifying to learn these results, even so, the fact that we are dealing with an oil-water fluid and a rise of only 5 ft. per day does not indicate to me, at all events, that this is a normal crude oil or that there is a substantial hydrostatic head below it in the "glauconite" (oil horizon). Without all the current facts it is difficult to assess the real position in this field, but at least it is to be hoped that, whether developed by standard methods or otherwise, some good use may be made of what oil is ultimately won, even if no petrol or light distillates can be refined from it.

H. B. MILNER.

RESEARCH ITEMS

India's Population

IN a paper entitled "Half a Century of Population Trends in India", in the *Geographical Journal* of Nov.–Dec., 1941, A. Geddes has worked out the population density of the administrative districts of India from the censuses of 1881 and 1931 and has plotted for each district not only the percentage change (increase or decrease) but also the variability or deviation from any steady rate of change. This entailed an examination of the figures of the intervening censuses. This method brings out many important considerations. Thus in Bengal the east shows high increase, with very low variability, in contrast to the west, which shows arrest without variability, or a state of stagnation. Rice lands of the south showed slight variability whether there was arrest, as in the Cauvery delta, or high increase, as in the deltas of the Kistna and Godavari. Broadly speaking, arrest or stagnation seems to be the outcome of deficiency of necessities and endemic diseases, while strong fluctuations about the mean, which might be accepted merely as arrest, are characteristic of the famine tracts. This is not a condition of stability, though, as Geddes points out, a careless reference to census figures might suggest that conclusion.

Influenza A Virus

Leslie A. Chambers and Werner Henle, of the Department of Pediatrics and the Johnson Foundation for Medical Physics, University of Pennsylvania, described work on influenza *A* virus before the American Philosophical Society on November 22. The infectious agent of influenza *A*, as it occurs in emulsions of infected mouse lung, is associated with particles about 100 mμ in diameter. Particles of similar size, chemical composition, density, staining properties and electron-microscopic appearance are derivable from normal lung tissue. Virus contained in the extra-embryonic fluids of infected chick embryos is not associated with such large structures, but may be absorbed completely from such fluids by the particles derived from normal lung tissue. This, together with other evidence, indicates that a component of normal cells may act as carrier of a considerably smaller pathogenic agent. Concentration of the virus from extra-embryonic fluids was accomplished by precipitation with protamine. Analysis of the resulting infectious complex indicates that the virus consists largely, if not entirely, of nucleoprotein. Ultra-centrifugation at about 90,000 gm. for 9 minutes sedimented almost all the infective material from egg fluids. Sedimentation diagrams of the resuspended sediment showed two components to be present. One of these gave a well-defined boundary and had a sedimentation constant of 31×10^{-13}, corresponding with a particle size of about 12–14 mμ and a molecular weight of about 1,000,000. Fractionation by ultra-centrifugation, followed by protein analysis and infectivity tests, indicated that the heavier, less homogeneous component (S_{20} = about $800 \pm 100 \times 10^{-13}$) consisted, almost entirely, of aggregates of the smaller units. The two sedimentable fractions were infectious in approximately equal dilutions. A minimal infectious dose contained about 10^{-16} gm. and therefore consisted of less than a hundred particles. A size distribution curve based on measurement of electronmicrographs of the isolated virus protein showed the particles to be essentially spherical and to have a modal diameter of about 11 mμ. This is in good agreement with the estimate based on the sedimentation constant, $S_{20} = 31 \times 10^{-13}$. In view of this evidence, the virus of influenza *A* is regarded as one of the smallest pathogenic agents yet isolated.

Parthenogenetic Activation of Rabbit Eggs

HERBERT SHAPIRO, of Hahnemann Medical College, Philadelphia, described the parthenogenetic activation of rabbit eggs in the unoperated animal at a meeting of the American Philosophical Society on November 22. It has been shown in earlier work that cold is an effective agent in initiating artificial parthenogenesis in rabbit ova *in vitro*. By inducing rabbits to ovulate as the result of a course of pituitary extract injections, tubal eggs of known age could be cooled *in situ* in the anæsthetized animal, under sterile surgical conditions, by circulating cold water through a metal jacket into which the tube was inserted. This mode of treatment did in one instance lead to the birth of a normal parthenogenetic female, capable of normal reproduction. In the present series of experiments, rabbit eggs were activated parthenogenetically in the intact animal, without operating surgically. Rabbits were made to ovulate as usual by pituitary injections. Cooling of the entire animal was effected by applying an ice pack on the doe's flank, directly over the region of the Fallopian tube, as she lay anæsthetized on the table. Rectal temperature, respiration and pulse-rate were recorded at regular intervals. The uterine tube, which lies just under the abdominal musculature, was very likely brought to a temperature lower than that indicated by the rectal thermometer. Body temperature (normally about 39·7° C. in the rabbit) was lowered to points varying from 33·6° C. to 18·0° C. In all experiments, perfect recovery of the animals occurred. Eggs were secured at various intervals after the experiment by flushing the Fallopian tube, and they were then fixed and sectioned for microscopic study. Artificial parthenogenetic activation was obtained in two animals, one of which contained two eggs in the two-cell stage, when examined forty hours after the activating treatment, and another contained a young embryo in the early morula stage. More advanced stages in embryogenesis have not thus far been obtained.

Leaf-Curl Virus Diseases

THREE leaf-curl diseases of plants in South Africa have been described by A. P. D. McClean (*Sci. Bull.*, No. 225, Dept. of Agr. and Forestry, Union of South Africa. Govt. Printer, Pretoria. Pp. 66; 6*d*. 1940). Leaf-curl virus of tobacco causes a yellow network on the leaves, followed by projection of the smaller veins, and finally the formation of leaf-like enations, with malformation of the foliage. It has been transmitted by White fly to a considerable range of Solanaceous hosts, and does not appear to be transmitted by mechanical means. Separate leaf-curl diseases have also been described on petunia and hollyhock. The former virus has been transmitted by grafting to tobacco, *Nicotiana glutinosa*, and tomato. It forms enations but no chlorotic pattern upon tobacco, and induces petal-like outgrowths from the corolla of petunia. Leaf-curl of the hollyhock induces chlorosis and emergent veins, but no enations.

Detection of Lactose and Maltose by means of Methylamine

W. R. Fearon described before the Society of Public Analysts and Other Analytical Chemists on February 4 a simple test based on the observation that when alkaline solutions of lactose or maltose are heated with methylamine hydrochloride under prescribed conditions a bright violet-carmine colour develops. The test shows concentrations of the sugars down to 0·05 per cent. The carmine colour is not given by other carbohydrates or related compounds tested, or by proteins, fats or biological secretions, such as saliva or urine. Other reducing sugars may be coloured yellow by the hot alkali, and in excess they may interfere more or less with the test by combining with the amine.

Decomposition of Carbonic Acid

The evolution of carbon dioxide from bicarbonate by mixture with acid is usually supposed to go in two stages, a practically instantaneous ionic reaction $H^{\cdot} + HCO_3' = H_2CO_3$, followed by a unimolecular time reaction $H_2CO_3 = H_2O + CO_2$. By using a calorimetric method in which the two solutions undergoing reaction are driven into a mixing chamber and thence into an observation tube in which the temperature is measured at several points, F. J. W. Roughton (*J. Amer. Chem. Soc.*, 63, 2930; 1941) has shown that these two stages actually occur. The separate heats of reaction were determined over a range of temperatures and also the velocity constant of the second reaction. The values of the equilibrium constant, $[CO_2]/[H_2CO_3] = 950$ at 0°, and of the first true ionization constant, $a_{H}a_{HCO_3}/[H_2CO_3] = 2\cdot5 \times 10^{-4}$ at 0°, were also calculated. The heat of the ionic reaction was found to vary with temperature in a manner characteristic of weak acids.

Atomic Weights of Silver, Bromine and Potassium

In a study of the thermal decomposition of potassium bromate, with a precise correction for the moisture content of the salt, and the comparison of pure potassium bromide with silver by precipitation as silver bromide, R. K. McAlpine and E. J. Bird (*J. Amer. Chem. Soc.*, 63, 2960; 1941) have obtained new values for the molecular weight of potassium bromide and the atomic weight of silver; and from these, by application of the ratio of bromine to silver from the work of Baxter and Hönigschmid, values for the atomic weights of bromine and potassium referred to the new value for silver have been calculated. The atomic weight of silver found is 107·879, agreeing within 1 part in 100,000 with the present accepted value. The atomic weights of bromine and potassium calculated from this and the ratio Br : Ag = 0·740786 are 79·915 and 39·096, respectively. On the basis of the international value Ag = 107·880, the atomic weight of potassium would be 39·095. These figures provide an important check on the work of Hönigschmid and Sachtleben on the atomic weight of silver, in which the absence of moisture in the barium perchlorate and barium chloride used was proved only indirectly.

Lower Oxides of Boron

In 1916 Travers, Ray and Gupta showed that when the residue from the repeated extraction of crude magnesium boride with water was treated with concentrated ammonia in an atmosphere of hydrogen the solution contained a substance of the composition $H_{12}B_4O_6\,2NH_3$, and when the ammoniacal solution is evaporated to dryness in a vacuum and gently heated, an oxide B_4O_5 remained, together with a small quantity of magnesia. R. C. Ray and P. C. Sinha (*J. Chem. Soc.*, 742; 1941) find that when the residue obtained by repeated and prolonged treatment with water of crude magnesium boride is kept in contact with successive portions of a fairly concentrated solution of ammonia in an atmosphere of hydrogen, and the filtrate concentrated in vacuum at room temperature, crystals separate from which, by fractional crystallization, two compounds, $(NH_4)_2B_2(OH)_2$ and $(NH_4)_2B_4O_6$, are obtained. When heated in a vacuum these formed powders of the oxides B_2O_2 and B_4O_5, respectively: $(NH_4)_2B_2(OH)_2 = B_2O_2 + 2H_2 + 2NH_3$, and $(NH_4)_2B_4O_6 = B_4O_5 + H_2O + 2NH_3$. The oxide B_4O_5 is perfectly colourless but B_2O_2 is slightly brown. The oxides are readily soluble in water, forming colourless solutions.

Sedimentation of Washed Red Blood Cells

The gradual development of biophysics is evident in occasional papers in the physical journals. A recent example comes from the Engineering Department of the University of Manchester, where R. B. Whittington has studied the sedimentation of washed red blood-cells (*Phil. Mag.*, 33, 68; 1942). The experiments were made as a first step towards a mechanical investigation of the red-cell sedimentation test, the sedimentation of whole-blood suspensions being too complex for direct mechanical study in the initial stages of the work. Although the red blood-cells approximate to elastic biconcave disks of diameter six times their thickness, they cannot be treated as non-biological material of the same dimensions. The suspending solution must be isotonic with blood-plasma. If the cells were suspended in a solution containing excess of salt they would shrink owing to loss of fluid by osmosis. A deficiency of salt would lead to swelling if not to rupture. Varying speeds of motion could not therefore be obtained by merely altering the specific gravity of the fluid unless it could be kept isotonic. Instead, a sodium chloride solution, 0·85 per cent by weight, was used throughout and the 'effective viscosity' was altered by varying the proportion of suspended cells. The drag-coefficients plotted logarithmically against the Reynolds' numbers gave a straight line graph.

Excessive Expansion of Dental Amalgams

Dentists have frequently been puzzled by an excessive expansion of dental amalgams. The normal expansion or setting is about 8 microns per cm. After 10–20 hours no further expansion should occur. Some specimens have, however, been found to expand more than two hundred microns in thirty days. The mystery has been solved by J. C. Schoonover and associates (*J. Franklin Inst.*, 232, 579; 1941). Records show that the excessive expansions occur only with alloys containing zinc and only in the presence of salt solutions such as NaCl. Gas pockets were found in such expanding amalgams, and the gas has been identified as hydrogen. Non-zinc alloys do not show this abnormal expansion, nor do zinc-containing alloys if they are amalgamated in a clean mortar or a mechanical amalgamator and are not contaminated by handling. The problem arose from the accidental introduction of NaCl from the perspiration of the palms of the hands of dentists when handling the alloys in the course of normal dental operations.

SEAWEED AS A FOOD FOR LIVESTOCK

By J. BEHARRELL

FACTS and figures concerning the extent to which seaweed in the form of a dried meal is incorporated in balanced rations for cattle, sheep, pigs and poultry are surprising and confirm the value placed upon seaweeds by the people of the Far East. Those who have lived in China know the value placed upon seaweeds. The Chinese import the dried product from the Pacific coast and use it daily as an important part of their diet; it forms one of the chief sources of supply of mineral salts. In the Hawaiian Islands more than seventy species of seaweed are reputed to have food value, but so far as is known no one has yet attempted to classify the world's Algæ, or even those of any country, according to their edible qualities. These appear to vary widely as to plants and in the parts of individual plants.

Among the most recent analysis of dried seaweed meals are those made in June 1939 by Dr. Bernard Dyer and Partners of London, which show the following:

	Norwegian	Scottish
Moisture	13·58	15·50
Oil or fat	4·40	1·50
Albuminoids	6·90	10·90
Digestible carbohydrates	53·95	35·30
Fibre	5·07	9·30
Ash	16·10	27·50
Mineral Matter		
Phosphoric acid	0·46	0·83
Lime	2·15	3·51
Magnesia	0·17	0·38
Sodium chloride	2·70	6·73
Soda in other forms	1·64	
Potassium iodide	0·07*	0·65†
,, chloride		4·98
Potassium in other forms	1·98	3·98
Iron oxide	0·10	0·32
Silica	0·20	1·40
Carbon dioxide, sulphur trioxide, etc. ...	6·63	4·72
Carotene	6·2	0·3

(parts per million)

* Equivalent to 500 parts iodine per million.
† Equivalent to 5,000 parts iodine per million.

While the analysis quoted gives the amounts of the major elements present—a spectrographic examination of the same product by the Macauley Institute for Soil Research carried out in March 1940 reveals the presence of sodium, calcium, magnesium and potash, with small quantities of barium, strontium and lithium and a trace of rubidium. Other elements observed in the ash were titanium, aluminium, iron, manganese, silicon and a trace of copper. The non-metals are not easily determined by spectrographic analysis, but the report states that copious iodine fumes were observed on ashing.

The concentrate, with the alkalis and alkaline earths removed, showed the presence of the following—quoted as parts per million of the original seaweed meal:

Cobalt	0·2	Vanadium	1
Nickel	10	Molybdenum	1
Tin	1	Gallium	0·5
Lead	1	Chromium	1
Silver	0·5	Lanthanum	10
Zirconium	3	Gold	
Zinc	40	Thorium	
Copper	10	Scandium	

The other trace elements mentioned are present in amounts of 1–10 p.p.m. but it was not possible to determine the exact percentages as no suitable standards were available.

This spectrographic analysis indicates the potential value of this product of the sea as a food for livestock.

Evidence of the value of seaweed for farm stock recently came from New Zealand (*Weekly News*, July 16, 1941).

The Laplanders feed seaweed to their cattle and so do the inhabitants of the Faroe Islands. In the Orkneys the magnificent stock is fed on seaweed as a proportion of their ration. At Stronsay in the Orkney Islands Laminaria is used. This is first dried by sun and air, being spread out thinly and treated as quickly as possible after being taken from the sea, otherwise it tends to decompose and is then unfit for stock feeding. Collection is made at all times of the year, but it is found by analysis that the iodine and mineral value is highest in the late summer and autumn. According to certain authorities it is an advantage to wash the weed and so remove any surplus salt.

The method employed in the north of Scotland is to dry the weed, and more particularly the long slender stipes (which are richer in iodine) by sun and air for several days, then to slice the latter by means of a special cutter, followed by a grinding process to reduce it to a fine grist.

This is finished on a rotary dryer—at a temperature varying from 350° C. to 450° C. for a period of forty minutes—and is later ground in the usual Christy and Norris type of disintegrator, when it is ready in fine meal form for blending in various types of feeding stuffs or in concentrates. The percentage used in the compound food is small, the usual rate being 1 per cent of the total food (by weight), but this can be increased to 2 per cent or slightly more with perfectly good results. Stock fed with this addition to their ration have increased stamina and a stronger resistance to disease. In the United States the Overbrook Dairy Herd, receiving dried seaweed meal in their ration, won the World's (Herd) Record for milk production.

A comparison between oats and a meal produced from dried *Laminaria flexicaulis* gathered on the coast of Brittany was actually made in a communication to the French Academy of Sciences in 1918. It gave the following figures:

	Oats	Dried Laminaria meal
Water	12·55	14·40
Carbohydrate matter	66·80	52·90
Nitrogenous ,, ...	9·10	17·30
Cellulose	8·45	11·50
Mineral matter	3·10	3·90

Results of feeding experiments gave 3 lb. of the meal as being equal in feeding value to 4 lb. of oats.

As 8–9 tons of fresh seaweed are required to dry down to 1 ton of fine meal, one million tons of seaweed would therefore produce the equivalent of 150,000 tons of oats, together with 1,200 tons of fertilizing material rich in potash.

It has been stated that in the islands of the Orkneys alone 30,000 tons of seaweed are available each year, so that the total quantity available round our coastline must be millions of tons.

With the backing of scientific research and practical feeding tests a vast reserve might be created to the great gain of our farmers and our stock feeders.

Present-day methods of gathering and processing by mechanical power might be improved—manufacturing costs, per ton, reduced to an economic level. There is evidence now that seaweed would provide food for farm animals in the years after the War, and profitable by-products for industry.

A considerable business has been created on the Californian coast to exploit the enormous jungles of giant kelp (*Macrocystis pyrifera*) which grows in the Pacific up to lengths of 500 ft. A machine mounted on a barge shears off the tops to a depth of three feet, which is the maximum permitted by the Government. Taken ashore, the kelp is treated in a similar way to that used in Scotland—dried in steam-heated or hot-air cookers, and ground to a fine powder, which must pass through a twenty-mesh sieve. The product is known as kelp meal and is mixed with a proportion of fish meal and sold as a seameal concentrate. Apparently not more than one tenth of the kelp meal harvested on the Pacific coast is prepared for stock food; all the rest is used for the extraction of iodine and for sodium salts.

The urgent need is for carefully checked records of the sea vegetation available, of the chemical value as a feeding stuff, for detailed digestibility trials, for the quantities required by stock to secure maximum results, and of its effect upon the health of all farm stock—a wide programme but one that should ultimately bring to agriculture thousands of tons of valuable home-grown feeding stuffs, from the sea-bed.

FORESTRY IN MALAYA

ONE reads with intensified interest the report of the progress of forestry in Malaya, now, we may trust for but a brief period, put to an end by the irruption of the Japanese. J. G. Watson, the head of the Forestry Department (if we omit the local inter-divisions of forestry administration of but little interest to the outside world), has written the "Annual Report on Forest Administration in Malaya including Brunei for the year 1940" (F.M.S. Govt. Press, Kuala Lumpur; 1941). In the report for the preceding year his predecessor, very fortunately as may now be thought, gave a valuable and interesting history of the growth of the Department from the year 1883 (see also NATURE, 148, 312; 1941).

In a general review of the year Mr. Watson mentions some small additional reservations of forest (347 square miles), bringing the total area of Government forest reserves to 10,879 square miles or 20·4 per cent of the total area. The actual area covered with forest of one type or another in Malaya is almost 77 per cent, 56·6 per cent of forest land being still unaccounted for. It is the existence of this mass of tropical forest covering the region which enabled the Japanese to penetrate so easily through the country.

Some interesting sylvicultural work was being undertaken, an all-Malayan regeneration *coupe* having been laid down for the conversion of inland forest. This annual *coupe* has been tentatively fixed at 12,088 acres; 1,000,000 acres have been set aside for this intensive management, of which 34,458 acres had been fully regenerated. The director of forestry says of this scheme that it is not yet fully operative in the more backward States where State land resources are still large. Differentiation between hard-wood and soft-wood areas is not possible as yet, but preference is given to those rich in the former. Eventual control will have to be on the basis of volume rather than area so far as hard-woods are concerned. It is sad to think that a certain proportion of this work will probably be lost, smothered by a victorious jungle of weed growth now that the attention of the forester will temporarily be no longer available. For those with a knowledge of the processes of growth in the tropical jungle are well aware that regeneration work of this kind can only be successful if carefully watched and given full assistance during the early critical periods. Already this work was becoming more difficult owing to the reduction of the staff through members joining the fighting forces.

This latter strain was, however, perhaps even more heavily felt in connexion with the timber industry and the numerous saw-mills of which there were eighty at work in connexion with the forests; fifteen of these mills are in the Straits Settlements (Singapore and Penang), forty-five in the Federated Malay States (Perak, Selangor, Negri Sembalin, Pahang) and twenty in the Unfederated States (Johore, Kedah, Perlis, Kelantan, Trengganu, Brunei). The combined outturn of all mills outside the Straits Settlements was 123,183 tons of 50 cub. ft. as compared with an estimate of 98,580 tons from Penang and Singapore. Apparently these two latter also saw up logs coming from Sumatra.

War conditions threw a heavy strain on the timber industry, which was (and, says the report, "will continue to be") hard put to meet emergency orders without dislocation of normal undertakings. The total outturn of logs was nearly 3,000,000 higher than the preceding year, the sawn timber running roughly each year at the same figure of 4,900,000 cub. ft. The one ply-wood factory produced 20,000,000 sq. ft. of three-ply sheets, and the four match factories seventy-three million boxes of forty matches apiece. The revenue from the forests during 1940 was 2¼ million dollars.

In spite of the absence of a number of officers detached to war duty, a certain amount of research work was continued throughout the year under various heads. It may be hoped, however, that when the department once again starts work in its forests more attention may be paid to preparing some working plans, the absence of which, in so advanced a department in many respects, is a curious anomaly.

If the annual report of 1940 is likely to be the last to be printed until the Japanese are sent out of Malaya, what can be said for the present prospects of the *Malayan Forester*, the December 1941 number of which has just been received?

An article on "The Contribution of Tropical Forests to War Economy", by H. E. Desch, wood technologist in the Forest Research Station in Malaya, is not without interest. In fact, it stresses without being aware of the fact, some of the dangers of the war exploitation of tropical forests already mentioned in NATURE. "A country rich in forests", says the author, "is obviously under an obligation to ensure that full use is made of its forests in War." This is undeniable, but it is just that "full use" in the case of the tropical forest which requires to be definitely understood. Too often the forest, at the mercy of the fellings of the timber merchant without expert supervision, has been ruined. The surprising demands which modern war make upon the forest are exemplified in a paper, "Forest Products and Defence", by C. P. Winslow, director of the U.S. Forest Products

Laboratory. To house a division of approximately 17,000 men in barracks requires 2,000,000 cub. ft. of timber; rather more than half if the men are quartered in a tent camp. Battleships are said to require 40,000 cub. ft. of timber and ocean transports 60,000 with an additional 300,000 sq. ft. of ply-wood, and so forth. The output of local sawn-timber and ply-wood in Malaya in 1940 has been already mentioned. Mr. Desch considered that the forests would be drawn upon to produce much larger amounts than that, and yet the forest service had already been called upon to allow a proportion of its gazetted staff to join the Forces. This was the position and in the absence of a recognition of the part played by the tropical forest in the economy of a country it appears probable that war demands would have similarly upset the good work which an excellent staff have been inaugurating during the past twenty years.

Mr. Desch regards this matter from the research and utilization point of view. His argument appears to be that the tropical forests of Malaya should be regarded as a source of sawn-timber and other produce for industries already existing in the country; but that their products should not be utilized for setting up, that is, supplying, the raw produce for new industries which, while interfering with the settled economy of the country, would require possibly new imports for their maintenance.

In how far the author's ideas would receive acceptance from the practical forest officer is open to doubt. But his ideas and these doubts must now remain for a future consideration.

SEISMIC PERIODICITY

This subject has been discussed by Archie Blake, who states that classical methods for detecting and measuring periodicity have suffered from two serious defects[1]. First, the Schuster periodogram does not provide adequately for non-sinusoidal types of variation. Secondly, the smoothness encountered in almost all time series and many other types of data introduces a spurious appearance of periodicity which vitiates the test of significance unless proper allowance is made for the smoothness. New statistics designed to detect effects not contemplated in the Schuster periodogram are being tried in a study of the series of aftershocks of the Helena Montana earthquakes of October 1935. This work is being done by use of punched cards, which greatly alleviate the labour of the computation.

In the case of two types of departure from randomness, such as periodicity and smoothness, each effect disturbs the statistics designed to detect the other. The only rigorous treatment is to study them together, but approximate methods (for example, that of Bartels) for discounting the effect of one type of variation in studying the statistics designed to detect the other may be very useful. Thus the accurate detection of periodicity demands a treatment of the problem of detecting, describing and measuring the smoothness exhibited by the series under test. This problem has been discussed by Bartels, Jeffreys and others, and from a different point of view by Shewhart.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Friday, March 13—Saturday, March 14

British Association for the Advancement of Science (Division for the Social and International Relations of Science) (at the Royal Institution, Albemarle Street, London, W.1).—Conference on "European Agriculture: Scientific Problems in Post-War Reconstruction".

Friday, March 13

10.15 a.m.—"Measures for Reconstruction". (Chairman: Sir John Russell, F.R.S.)

2.15 p.m.—"Economic and Kindred Problems". (Chairman: Mr. F. L. McDougall.)

Saturday, March 14

10.15 a.m.—"The Future Betterment of European Farming". (Chairman: Dr. A. J. Drexel Biddle.)

2.15 p.m.—(Chairman: Sir John Russell, F.R.S.)

Monday, March 16

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. H. P. Rooksby: "X-Ray Technique in the Industrial Laboratory" (Cantor Lecture, 1).

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5 p.m.—Colonel Orde Wingate: "Geography of the Ethiopian Campaign".

Tuesday, March 17

Royal Society of Arts (Dominions and Colonies Section) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. Ernest Marsden: "Recent Developments in the Scientific and Industrial Research Programme of New Zealand".

Chadwick Public Lecture (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 2.30 p.m.—Dr. William A. Brend: "Nervous Shock in Peace and War".*

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir Lawrence Bragg, F.R.S.: "Metals", 3: "Magnetic Properties of Metals".*

Royal Statistical Society (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Mr. R. G. Glenday: "Economic Reconstruction after the War".

Wednesday, March 18

Oil and Colour Chemists' Association (Manchester Section) (at the Engineers' Club, Albert Square, Manchester), at 2 p.m.—Dr. J. G. Gillan: "Some Aspects of Camouflage".

Institute of Physics (Joint Meeting of the London and Home Counties' Branch and the London and South-Eastern Counties' Section of the Institute of Chemistry) (at the Royal Institution, Albemarle Street, London, W.1), at 2.30 p.m.—Prof. H. Levy: "Social Implications of Science in War-Time".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 4.30 p.m.—Dr. H. Spencer Jones, F.R.S.: "The Atmosphere of the Planets" (Symons Memorial Lecture).

Thursday, March 19

Institute of Fuel (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 2.30 p.m.—Dr. Ezer Griffiths, F.R.S., Dr. R. W. Powell, and Mr. M. J. Hickman: "Thermal Conductivity of Some Industrial Materials".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 6 p.m.—Dr. A. P. M. Fleming: "A Critical Review of Education and Training for Engineers".

Friday, March 20

Physical Society (in the Lecture Theatre of the Science Museum, Exhibition Road, London, S.W.7), at 4.30 p.m.—Sir Edward Appleton, F.R.S.: "Ionospheric Influences on Geomagnetism" (26th Guthrie Lecture).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (man or woman) in Pharmaceutical Subjects in the Plymouth and Devonport Technical College—The Director of Education, Education Offices, Cobourg Street, Plymouth (March 18).

Technical and Constructional Assistant in the Borough of Luton Electricity Undertaking—The General Manager and Chief Engineer, Electricity Offices, St. Mary's Road, Luton (March 20).

Lecturer in Engineering Subjects in the Cardiff Technical College—The Director of Education, City Hall, Cardiff (March 25).

Assistant Drainage Officer to the Lancashire War Agricultural Committee—The Executive Officer, Institute of Agriculture, Hutton Preston (March 28).

Colloid Chemist or Physicist—The Director of Research, British Pottery Research Association, Queens Road, Penkhull, Stoke-on Trent.

University College of Science
PHYSICS Dept.
92, Upper Circular Rd, Calcutta.

A SCIENTIFIC FOOD POLICY

WAR had brought famine to two of its first victims, China and Spain, before Great Britain took part in it. With the deliberate spoliation by the Nazis, the blockade and the scorched earth policy in the most fertile regions of the U.S.S.R., famine at the end of this War will be far worse than in 1918 and the following years. Some form of international famine relief commission must, perforce, be set up. It may be content to restore the unsatisfactory normal of the years before the War, or it may grow into a permanent organization that will attempt to raise the nutrition of people throughout the world to a satisfactory level—an organization that will differ from the wistful and ineffective League of Nations in having executive powers. If the present determination to make a safer and saner world survives the War, this relief organization will not give up the more ambitious aim.

Of the four freedoms of President Roosevelt, freedom from want, in respect of food at any rate, stands in a class by itself. Such phrases as freedom of speech may have very different meanings in New York and Moscow, in London and in Berlin ; even those to whom the words carry the same meaning, may differ in their estimates of the amount of freedom that should be allowed. But a calorie is a calorie all the world over ; the experts of nine States have agreed on the minimum amounts of various food constituents that freedom from want implies. The requirements are settled. How can the supplies be obtained and how can a fair distribution be ensured ?

We can take it that plans for the reorganization of British agriculture that suited the years before the War will no longer meet our needs. The economic position of Great Britain will have changed fundamentally ; we shall no longer be able to draw food and feeding-stuffs, as tribute, from half the world. Further, as Dr. Platt said at the recent meeting of the Nutrition Society (see p. 318), continued importation of large amounts of feeding-stuffs by Great Britain does not involve a competition for food between different kinds of domestic animals only, or even between men and animals only, but also between men and men ; the food for our animals is taken at the expense of men in other parts of the world. There are huge blocks of human life, in India and China, for example, whose standard of diet is not of the same order as the minimum proposed by the Technical Commission of the League of Nations or as the standard of diet of western Europe. Europe, excluding the U.S.S.R., with a population little more than one third that of Asia, consumes more cereals and six times as much meat. A world of such gross inequalities cannot be stable.

Physiologists have been impressed by the production (over a limited area and for a limited period) of supplies of food in excess of effective demand, and by the deliberate destruction and limitation of productive resources. They have been inclined to believe that there is no physical bar to the satisfaction of their demand for adequate food for all ; that ample is available to order. There is an opposite view; in its extreme form it is that human nutrition is a by-product of a cycle—fodder crops, animals, manure—that maintains the fertility of the soil. The exhaustion of the soil, which has reduced fertile land from Saskatchewan to Texas to whirling dust, has made us all realize that the soil cannot supply food in unlimited amounts and kind; that it is essential to plan the type of food produced so that the quality of the soil will be maintained. If this is not done in the traditional way with animal manure, some other way must be found.

Actually the world, as a whole, has never produced too many calories for human food; certainly, in the years after this War there will be no excess. It will be necessary to take care of the calories. Now, the largest number of calories for human consumption can be obtained from a given area if crops are grown that can be eaten by human beings. If feeding-stuffs are grown and used to feed animals, the return, in terms of calories, is poor. For example, an acre under potatoes will produce some four million (large or kilo-) calories for human consumption, and some two million if under wheat; but only one fifth of a million calories if used as grass-land for feeding beef cattle, and two thirds of a million if used to feed milch cows. Animals, like human beings, use up the greater part of their food to supply their daily needs of energy, and store only a small surplus as flesh; owing to the rapid growth of animals, the return is higher than might have been expected. But, during periods when calories are short, no more animals should be kept than are needed to maintain the fertility of the soil (supposing that no substitute is found) and to meet the special needs of human beings that are not well supplied by vegetables. The conversion factors give a fairly correct estimate of the relation between the amount of energy, for human beings, obtained if crops are used direct as human food and the amounts obtained if the crops are used indirectly for feeding animals which are eaten by human beings; for a calorie is much the same, whether obtained from animal or vegetable food.

But estimates of the amounts of protein produced by animals from a given amount of protein in feeding-stuffs cannot be used without qualification; they do not take into account the difficult question of biological value. Meat is of special importance in nutrition because animals pick out the indispensable amino-acids, which we cannot make ourselves from their food, and concentrate them in their flesh. The concept of biological value is unsatisfactory. It appears that wheat protein mixed with a small amount of animal protein may have the same value as an equal weight of animal protein. We cannot calculate the proportion of vegetable food to meat that will give the highest nutritive value per acre until we have a more exact knowledge of the metabolism of amino-acids and of their interplay. However, milk is in a class by itself; milch cows give a fairly high return, even of calories; the protein of milk has a high biological value; cows concentrate calcium and riboflavin in their milk; they return the carotene of their food mainly as pre-formed vitamin A, which is better absorbed by human beings. Taken all round, milch cows are by far the most efficient converters of vegetable feeding-stuffs into valuable food for human consumption. In times of shortage they are the only animals that should be allowed to compete with human beings for food; other animals, male calves, for example, should be killed young.

This concentration on vegetable crops, for direct human consumption, and on milk and milk products, gives the diet recommended by Sir John Orr both for war-time and during the reorganization of the world's food supply. So far as our present knowledge goes, it will supply everything that is needed.

At the end of the meeting of the Nutrition Society on February 28, Sir Joseph Barcroft stressed the importance of the flavour and interest of food. But there is no reason why milk products and vegetables should be flavourless or dull. There is a wonderful choice of cheeses, and no two Cheddars even taste quite the same. There is no need to cling to the narrow range of badly cooked vegetables that is traditional in Great Britain. What is wanted is better methods of transporting and storing vegetables, something comparable with the improvement in methods of storing fruit. As it is, however, the diets of many people are so dull that they must enliven them with crude flavourings. The Indian corrodes his stomach with curry and the Englishman spoils his palate and ruins his digestion with pickles and spices. The first edition of 'Blitz' soup, prepared to suit the taste of Londoners, was so fiery that it might have been used externally as a counter-irritant. Further, tastes are changing. British soldiers patronized milk bars, so long as they supplied milk. Experiments on children have been extended to adults eating in canteens; one can now see sturdy draymen sampling Oslo meals.

Vegetables and milk are best produced on the spot, whereas cereals are well suited for transport. The most effective policy would be one similar to the breadstuffs policy of the War of 1914–18. Peoples, such as those of India and China, who now wring just enough or not enough calories from the soil, might be supplied with cereals from areas such as Canada and the Argentine that can expand production and produce a surplus over their requirements. In this way, land in the over-populated countries could be set free for growing other crops and for feeding animals, with benefit to the health of the people and the fertility of the soil.

If the amount and quality of food is to be raised, agricultural machinery must be supplied. This will involve an increased demand on manufacturers, who will have to meet other demands to supply pressing needs—machinery for transport and building, for example. The Nutrition Society is a valuable meeting-place, in which physiologists can discuss with agriculturists how best their demands can be met. Should there not be a means devised of enabling agriculturists to meet manufacturers, state their requirements and learn the difficulties that may lie in the way of their fulfilment?

There are political difficulties, too. Small farms cannot use agricultural machinery economically. There must be some form of amalgamation, whether in State farms, collective farms, co-operatives or large groups of family units under one management. In China some 40 per cent of farms are less than 1⅔ acres; in Japan two thirds are less than 2½ acres. These little plots cannot produce proper food for the farmers' families. Some means must be found by which the density of the agricultural population can be reduced.

The production of sufficient food is only half the battle. The producer must know that his crops will find a market; the consumer must be able to buy the food produced. The whole reorganization must involve fundamental changes of custom and conflict with vested interests. Opposition may be less than it would have been a few years ago. All the world over, people are becoming familiar with food control; in Great Britain they are beginning to realize its possibilities. Also hunger is a strong argument, and hunger is one of the few things of which there is prospect of plenty at the end of the War. An International Famine Relief Commission will wield a convincing weapon—food; if it uses this weapon justly and efficiently it can do much to reconcile people to profound changes. Difficulties are great; they must be studied now. For only those who know clearly what they want and how to get it are likely to achieve anything worth having in the welter of conflicting policies at the end of the War.

INTERNATIONAL ECONOMIC EQUILIBRIUM

THE meetings of the Inter-Allied Council render one signal service in respect of reconstruction—they stress its international aspect. This has to some extent been overlooked in the studies and discussions on reconstruction which have so far been initiated in Great Britain, and for all the attention that has been given to the work of the Leith-Ross Committee and the establishment of the Leith-Ross Bureau to deal with problems involved in the storage of surplus foodstuffs and their distribution after the War to the peoples in enemy-occupied Europe, the economic aims stated in the fourth and fifth points of the Atlantic Charter have not received much emphasis. The political, economic and social aspects of international reconstruction cannot indeed be entirely separated. They are as interlocked as the international and the national or internal aspects of reconstruction, and our hopes of a new and stable world order depend largely on our exploring the situation now so as to lay bare the principles for a constructive policy in readiness for the time of action.

Much of that action must of necessity be deferred until after the War, though in certain matters preliminary action as well as the determination of broad lines of policy are already required. Demobilization, for example, clearly must receive consideration before the fighting ceases. Plans must be in readiness, and the experience of 1918 is with us as a warning that a sudden and unexpected collapse of the enemy should not again find us unprepared. Unpreparedness can as assuredly endanger the winning of the peace as it has hindered the organization of victory.

In the last year or so, the discussions which for the first year of the War were so prominent on Federal Union and the exact form of the organization of a collective security system have rather fallen into the background. It has been recognized that the final form of organization to be adopted is a question to be determined later. On the other hand, there is a wider recognition that forms of co-operation established to serve the common purpose during the War can equally contribute to the final purpose of winning the peace. Even before the United States entered the War, there was unmistakable evidence on both sides of the Atlantic of Anglo-American determination to maintain that co-operation, and the machinery now established will not be recklessly scrapped unless it is proved to be no longer serviceable.

Besides this, attention is being concentrated, not first on the machinery to be established, but rather on the problems to be solved, with the object of elucidating first principles and from them arriving at the methods and organization most likely to provide a solution. In the field of international reconstruction there is, for example, the problem of the relation of Great Britain to Europe. There is the problem of the place of Germany in a new European system. There are the questions of the colonial peoples and of raw materials, and there is the problem of reconstructing world trade.

All these problems are, of course, related and have at least some bearing on the organization of post-war relief in occupied Europe, as well as on the establishment of a new system of collective defence. None the less, they can each serve as the starting-point for an attempt to arrive at first principles and to remove some of the causes of international friction which contributed to the outbreak of the present struggle. This is admirably illustrated in the survey of international economic relations which Prof. J. B. Condliffe has written under the title "The Reconstruction of World Trade"*.

Prof. Condliffe's volume falls naturally into three parts. The first analyses the collapse of the international trading system that was restored, on the pre-war model, after the War of 1914–18. The second, including much the most technical chapters, examines the challenge now presented by the totalitarian methods of bilateral trade. The third surveys the problems that must be faced in any attempt to reconstruct world trade after the War comes to an end. The book is based largely on material drawn from research studies undertaken in preparation for a conference called to meet at Bergen on August 27, 1939, and much of it would normally have formed a report of the International Studies Conference on "Economic Policies in Relation to World Peace". It has, however, lost nothing of its pertinence in the interval, and this lucid exposition could scarcely be bettered as a guide to the discussion of trade policy after the War to which Mr. J. G. Winant and Mr. Sumner Welles have recently made such pointed reference.

---

* The Reconstruction of World Trade: a Survey of Internationa Economic Relations. By Prof. J. B. Condliffe. (Prometheus Library.) Pp. 427. (London: George Allen and Unwin, Ltd., 1941.) 12*s*. 6*d*. net.

On the making of policy Prof. Condliffe writes forcefully in his opening chapter. He points out that a Government can rarely lay down in advance, and adhere to, a line of policy which is the result of mature judgment and reflection. Wherever action must be adjusted to an ever-changing set of circumstances largely beyond the control of any individual, group, or government, policy must be in large degree improvised and pragmatic.' Moreover, a discussion of the forces that shape national economic policies in the international field cannot be narrowly confined to the field of commercial policy. Prof. Condliffe refers pointedly to the effect of private enterprise, and it follows from what he says that any serious attempt to achieve a balance between freedom and order in the national sphere, as has been suggested by Mr. Geoffrey Crowther, is bound to determine largely the nature of economic policy in the international field.

A further important factor is the passing of power in recent years from the legislative to the administrative side of government. This is widely recognized, but its bearing on economic policy has scarcely been examined, and the searching questions which Prof. Condliffe raises demand careful answer if our reconstruction of world trade is to proceed on sound lines. He stresses the real danger of the progressive withdrawal of day-to-day policy from detailed public scrutiny and criticism. The concentration of power exercised for long periods without the check of public criticism makes individual errors more serious, because errors of policy tend to become cumulative. Moreover, administrative control of policy-making puts a premium upon organized pressure from directly interested individuals or groups of individuals, and lessens the consideration likely to be given to the general public interest, and particularly the unorganized interest of the consumer.

These warnings cannot be lightly disregarded in respect of whatever new measures of commodity control may be developed even for the relief of occupied European countries. The conflict between national regulation and international equilibrium must be recognized, and while we may seek, as Prof. Staley has urged in "World Economy in Transition", to lessen the economic significance of national boundaries, the task of creating effective organs of international co-operation on a regulated basis must not be shirked. Meanwhile Prof. Condliffe's conclusion that the best practical prospect of restoring international equilibrium lies in the re-establishment of known and accepted routine lines of policy, based upon a relatively moderate degree of national planning in the sense of assuring to each national community reasonable minima of security and livelihood, is at least in keeping with the terms of the Atlantic Charter. World economic activity, like world peace, is in fact indivisible.

The relation of freedom of trade to the establishment of social security in the field of nutrition has already been emphasized in such studies as F. L. McDougall's "Food and Welfare", and Prof. Condliffe's book shows how closely it is related to the wider aspects of security. Government policy, not economic or scientific developments, has been responsible for the great decrease in trade in agricultural products, both food and raw materials. The primary responsibility for the breakdown in international trade lies not with economic facts but with economic policy, arising from attempts to place the interest of particular groups before that of the community as a whole and, in particular, to preserve and buttress the unfettered sovereignty of the national State.

International economic equilibrium is not a static but a dynamic concept, and we have yet to develop the appropriate organization and technique now that the technical progress of industry has outgrown national boundaries, as in an earlier age it outgrew the boundaries of city States. Social regression, not security, will follow from any attempt after the War to cling to traditional forms of political organization and put back the clock of scientific knowledge and industrial technique. The dangers inherent in modern tariffs and the complications of tariff bargaining, the administrative obstacles they introduce to trade and the extent to which they represent a reversion to tyrannical methods of government are unmistakable in this analysis. Bilateral treaties negotiated in recent years represent, on the whole, grave restrictions on multilateral trade, and the warm tribute which Prof. Condliffe pays to Mr. Cordell Hull's efforts to promote multilateral trade and breach the high protective wall erected by the Howley-Smart tariff does not disguise the little that had been achieved in removing the obstacles to the restoration of world trade.

It must be recognized therefore that while attempts to preserve past privileges of occupation or ownership may wreck international co-operation in the future as they have done in the past, the absence of any real will-power has been the decisive factor. Policies of independent economic nationalism can never form the basis of co-operation. Their ultimate aim is world domination and their technique is that of conflict. No compromise is possible, in the long run, between States that are organized to serve the purposes of individual citizens and those in which the individual is subordinated to the service of the State.

Prof. Condliffe's thoughtful chapter on new aspects of international organization well illustrates the need for further investigation if we are to formulate a sound policy for the reconstruction of world trade. We have to take account, not merely of the limitation or redefinition of national sovereignty, but also of the tendency of business organization and trading relations to become international in scope. The importance of the borderland between business and government with regard to international relations has increased considerably and still presents one of the most significant fields for economic research. Moreover, experience gained with certain of the war-time controls can scarcely fail to prove invaluable for the correction of the weaknesses revealed in some of the pre-war international commodity control schemes and to increase our exact knowledge of their extent and relations with government regulation. If Prof.

Condliffe does not visualize anything like the Raw Materials Union suggested by "Balbus" in "Reconstruction and World Peace" (Democratic Order Pamphlet No. 10) and in the P E P broadsheet, "Commodity Control Schemes", he at least sees the possibility of dealing with the consumer interests more fairly and effectively.

The extension or development of international commodity schemes is a difficult problem. There is no very satisfactory half-way house between a free trading system based on *laisser-faire* and one in which national production is co-ordinated in a system of international planning. Moreover, Prof. Condliffe has misgivings about the international planning of policy, for reasons already indicated, and while he considers there are wide areas of economic activity over which government control could with advantage be extended, such control should be limited to regulation rather than operation, and for this new types of international political and economic institutions must be invented. Indeed, the possibilities of international economic co-operation in the immediate future will largely depend on the way in which governments use such powerful new instruments as credit regulation.

While the necessities and disillusions which follow a great war may be powerful factors of constructive co-operation, that only holds if they are used in that direction. Peace is a dynamic process, the other name for which is co-operation, and only a world which is prepared to make the continuous effort of re-creating peace, like freedom, year by year, can establish and maintain a new international system of economic co-operation and social security. The most hopeful feature of that Anglo-American co-operation which has developed during the last fifteen months has been the frank indication on both sides of the intention to see it to completion.

Prof. Condliffe recognizes the paramount influence of the United States on any international system vhich can be established, and that it must be based n Anglo-American co-operation. He touches on ose other problems of the position of Britain in rope which also affect the ultimate solution, and esses that the choice before us is broadly one tween entering a European confederation or joing with the United States in an effort to re-establish a world trading system. But it is less for the outline of a suggested solution of the problem than for its clear analysis of principles, its firm warnings of the angers that cumber the way, its challenge to search- g inquiry and constructive thought that Prof. ndliffe's book is an outstanding contribution to discussions which Mr. Winant, Mr. Cordell Hull, Sumner Welles and others have already initiated. he guarded language which Lord Cranborne essarily used in November in replying to a question the House of Lords regarding the methods by which e Government proposes to give effect to Article V the Atlantic Charter and to secure the fullest llaboration between all nations in the economic d should not be taken as indicating that the vernment is not alive to the importance of this ject and anxious to secure the improved labour standards, economic advancement and social security implied therein. Practical plans of economic co-operation already engage its attention, and the growing ties between the two great democracies should ensure that they will face together now, and not merely after the War, the broad changes of policy involved in the inevitable internal and external reconstruction. Moreover, in approaching and studying these problems it must be remembered that by the adhesion of the Soviet Union and of the Allied Governments now in London, the Atlantic Charter has become a multilateral pact. The co-operation of twenty-six nations in fighting aggression is already pledged thereby to continue after victory is won to ensure that the world shall gather its fruits in peace and in security.

The immediate task in regard to world trade is of course to create the international machinery for co-operation after the War to enable people to live, to find the means of livelihood, and to exchange their products with one another, and to arrive at common understanding as to the principles on which such machinery shall operate in the conditions likely to obtain at the end of the War. The impartial examination of practical problems in a new setting, without regard to theories or dogmas framed to meet other conditions, should be able to evolve plans for preventing a repetition of the chaos which followed 1918. The four freedoms will only be established by planning and co-operation and an immense amount of hard work, in which the reconstruction of world trade is one of the first steps to the establishment of that freedom from want, which in Mr. Winant's view should be one of our first objectives after the War. There should be no lack of response in Great Britain to the efforts already being made in the United States in the study of these problems, so as to extend the present co-operation after the War into the organization of the exchange of goods on co-operative instead of on narrowly competitive lines.

WEATHER ANALYSIS AND FORECASTING

Weather Analysis and Forecasting

A Textbook on Synoptic Meteorology. By Prof. Sverre Petterssen. Pp. xvi+505. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 35*s*.

FOR twenty years the Norwegian school of meteorology has led the world in the development of methods of forecasting. The appearance of a treatise on weather analysis and forecasting by a distinguished member of the school is therefore an important event. Prof. Sverre Petterssen was for many years on the staff of the Geophysical Institute at Bergen and recently succeeded Prof. C. G. Rossby as professor of meteorology at the Massachusetts Institute of Technology. His book developed from courses of lectures delivered during the years 1935–40 at various places in America and Norway.

Long before the influence of the Norwegian school was felt, meteorologists realized that the weather was influenced largely by the interplay of currents of air from different parts of the globe. Occasionally, when contrasts of temperature were great, boundaries were drawn on a series of maps and the progress of such boundaries, which were frequently marked by line-squalls, was traced from map to map. The new school introduced the practice of drawing these boundaries or ‘fronts’ between different ‘air masses’ on every working chart. It was soon manifest that the charts gave much more vivid pictures of the weather over large areas than had ever been obtained before. A striking development was the recognition of the fact that the isobars, when carefully drawn, are kinked where they cross fronts. When once the eye is trained to look for these kinks, one wonders how the meteorologists of yesterday could have drawn smooth isobars through the areas where the wind distribution cried out for sharp bends. Modern forecasting depends largely on the study of the movements of fronts.

In the rules for forecasting developed by Petterssen, great stress is laid on arithmetical calculation. He is not content to notice that a front or any other feature of the weather map is moving towards the east. He works out the speed at which the feature has been moving and finds that, if all goes well, the feature will have travelled so far in the next twenty-four hours. The rules which are propounded are simple enough. They could have been introduced as soon as the practice of reporting the barometric tendency (the change of pressure in three hours) was initiated in the weather reports from telegraphic stations. The general rule is that any well-marked feature of the weather map will probably continue for several hours to move as it has been moving. The rule is reduced in each case to an appropriate numerical formula, which justifies the author’s bold quotation, on the flyleaf facing his title-page, of Lord Kelvin’s dictum :

“When you can measure what you are speaking about and express it in numbers, you know something about it ; but when you cannot measure it, when you cannot express it in numbers, your knowledge is of a meagre, unsatisfactory kind.”

In the main, the processes developed by Petterssen are purely kinematical, the map is regarded merely as the representation of a moving, changing pattern, but use is made of the idea of the gradient wind in four of the thirty-one rules that are set out.

The individual forecasts which are quoted are remarkably accurate. While the forecasts of the movements of systems are purely kinematic, depending solely on the first law of motion, the deductions as to the resulting weather are made with an intimate appreciation of the effects of the varying structure of air masses with different histories.

It might have been expected that the upper air observations available to the forecaster would have been brought into these numerical forecasts. Actually, in Petterssen’s own scheme the information available serves rather to give the structure of the atmosphere in the several air masses and in defining the positions of the fronts. However, that is not the end of the matter. It is an important question to the forecaster this, how to make the best use of the upper air observations which are obtained by special aeroplane ascents and, in the most modern technique, by radio soundings. The system adopted in the United States, where such observations are now well distributed, is to map temperature and humidity corresponding with an isentropic surface, that is, a surface on which the potential temperature of air (the temperature to which it would be brought by adiabatic compression to the standard pressure 1000 mb.) has a constant value, such as 26° C. This way of representing the conditions in the upper air was first suggested by Sir Napier Shaw. It has the advantage that a single set of lines represents the distribution of temperature, pressure and density. Further, so long as the air is not affected appreciably by radiation, conduction and turbulence, it must move on an isentropic surface. Rossby, who developed the practice of using isentropic charts, found it useful to show humidity by the proportion of water vapour in the air. The way in which the vapour is conveyed from region to region across the continent is portrayed most vividly. The valuable chapter on this subject is contributed to the book under notice by Mr. James Namias, who was Rossby’s collaborator at the Massachusetts Institute of Technology. The method is also illustrated in the last of the forecasting studies in the work.

It would be presumptuous for a reviewer with no practical experience of forecasting to assess the value of the book to the working forecaster. It may be said, however, without fear of contradiction, that to the layman who has already some familiarity with meteorological charts, the book is most acceptable for the insight it gives into the principles on which modern forecasting is based.

F. J. W. WHIPPLE.

PRESERVATION OF ORNAMENTAL TREES

Maintenance of Shade and Ornamental Trees
By Prof. P. P. Pirone. Pp. xvii+422. (New York and London : Oxford University Press, 1941.) 25*s*. 6*d*. net.

SO much can be done with trees to clothe the nakedness of arterial roads and to screen from view the hasty work of the builder in new ‘development’ schemes that a book designed to assist in establishing and protecting trees is welcome. There are districts where it is impossible to restore the ‘rustic scene’ but where, given time, avenues, say, o horsechestnut, or groups by the roadside of suc trees as beech, birch or Norway maple, compensa to some extent for lost amenity. As for trees urban areas there is the example of New York Ci quoted by the author, where nearly a million tr are maintained along some five thousand miles streets.

In the years which immediately preceded the War there was an awakening of the public conscience to the æsthetic value of trees, and societies such as the Council for the Preservation of Rural England an the Roads Beautifying Association did much direct attention to the subject. Numerous bo have appeared dealing with ornamental trees an few have confined their attention to ‘tree surge still there is room for Dr. Pirone’s volume on ‘m tenance’.

The author addresses himself specifically to eastern and mid-western States of America, l readers will find plenty of suggestions applicable conditions in Great Britain.

The author wastes no time in preliminary d cussion; after a brief preface and an introduct note by Dr. L. H. Bailey, he plunges straightv into a concise description of the structure of a t and the functions performed by the various parts. The relation of soil to tree growth is then approached, particularly as regards the soil's physical state and chemical composition, but not forgetting the biological aspect. Emphasis is laid on the importance of the degree of soil acidity or alkalinity, as the case may be, in determining the choice of species. In this connexion a list is given of the *p*H range suitable for the commoner trees and shrubs. If due weight be attached to the other factors, such as elevation, exposure, rainfall, etc., the relative *p*H value will be found to be a useful guide. It is pointed out that most trees prefer soils with a slightly acid reaction, but requirements vary a great deal from the lime-loving to the peat-loving species.

As regards the planting of trees, the author remarks that the methods employed too often resemble an experiment to see how much the tree will stand. Instead of this, of course, the effort should be to reduce so far as possible the shock of removal and to give the transplanted tree a good start. It may be that very few planters will be able fully to follow the author's somewhat elaborate prescriptions, especially in war-time, but it is well to be reminded of the care that should be taken, particularly when trees of large size are being transplanted.

Pruning and the treatment of wounds naturally claim considerable space in this book, for the number of wrong ways of proceeding is remarkable. In Great Britain the section will command the greater attention owing to the unusual amount of damage caused in recent winters by ice and snow. Most of the damage, unfortunately, has perforce been neglected, and wood-attacking fungi will undoubtedly gain a footing if pruning is much longer delayed. To rid trees of their lower branches and produce straight, clean stems is another and quite distinct problem for the pruner which the author discusses, but he makes no mention of 'natural' pruning so familiar and so useful to the forester. It may have been considered outside the province of the 'arborist'. But is it ? In parks, at least, trees can be grown in groups just as easily as singly, and even if individual trees are eventually isolated, the good effects of early massing will be observable in better shape, health and vigour.

Neglected bark-wounds and the removal of large ranches so often lead to decay that a description of e methods of repair forms a fitting sequel to the pter on pruning. The notes on various matters cerning this kind of surgery include specifications he antiseptic dressing of tree wounds and are nctly helpful. As for the treatment of cavities ee trunks, however, it appears doubtful if it is better, in most cases, to let well alone rather to plaster the holes with incongruous stuff such ment, bricks, clay, mortar and asphalt. Gener- peaking, these attempts at arresting decay are and the unsightly patchwork strikes a jarring

aders who turn to the section headed "Trees ole for Streets and Roadsides" will be disap- ed to find that only about fifteen species are with and some of these are dismissed in half a n lines. Many beautiful trees quite well adapted he purpose, such as birch, hornbeam, whitebeam, ring cherries, hawthorns, Nothofagus, Pyrus, itschia, etc., are omitted altogether, or mentioned vhere in the book only in connexion with the ents which occasionally afflict them. Small and ium-sized trees are in many cases more desirable n larger trees for bordering motor roads as their finer leaves decompose more readily and do not cause a skiddy surface.

Passing on to the diseases and insect enemies of trees, we find a somewhat undue proportion (half) of the book is occupied with their discussion. It is to be hoped that would-be planters will not be discouraged by the number and variety of pests, because, apart from a few diseases, for example, chestnut blight and the Dutch elm disease, single trees (as distinct from trees in massed formation) are fairly free from serious infestation. The list of possible dangers—parasitic, non-parasitic and climatic—has an alarming appearance rather out of proportion to the actual risk. Still, if not taken too seriously, there is always the biological interest of diagnosing ailments, studying the pathological symptoms and occasionally endeavouring to treat the complaint. These matters are dealt with helpfully in the text and excellent photographs assist identification.

The book is handsomely turned out, being well printed, well bound, fully illustrated, and provided with a good index and an extensive bibliography. It deserves a good reception from all who have anything to do with the planting and preservation of park, street and roadside trees. Its perusal should correct any tendency to haphazard planting and lead to the better maintenance of the beautiful trees which already adorn the English countryside.

FRASER STORY.

AN INDIVIDUALIST'S PHILOSOPHY

Brought Out in Evidence

An Autobiographical Summing-Up. By William Bowyer. Pp. 424. (London: Faber and Faber, Ltd., 1941.) 15*s*. net.

THIS book is at once a presentation of the author's beliefs about the universe and the record of his own life. Save in the opening chapter, entitled "The Horizon", where he garners the ripe fruits of his spiritual pilgrimage, the philosophy is, with rare artistry, interwoven with the autobiography. Mr. Bowyer could scarcely have done otherwise ; for his speculative outlook is intensely personal. Born in a Battersea slum, into a house clouded by dissension and poverty, where religion meant little but the crude and jealous fundamentalism of Plymouth Brethren and of Strict and Open Baptists ; educated (*sic*) in the elementary and grammar schools of the locality ; harnessed while still a lad to the drudgery of a subordinate post in the General Post Office—such an upbringing was bound to leave an enduring mark on a nature shy, awkward and inarticulate, and at the same time richly gifted and responsive to every stimulus that crossed its path. He hungered for the friendship of those who 'cared' for the things nearest his heart.

Mr. Bowyer is too much of the artist in temperament to rank as a philosopher. His creed is avowedly intuitional, a matter of faith rather than of reasoned evidence. Like D. H. Lawrence, for whose mind he confesses "an awed admiration", he profoundly distrusts the analytic method of the sciences, a distaste probably not lessened by the suspicion that he offers an appetizing bait to the psycho-analyst. No wonder that he early swung free of materialism and scientific determinism, as later on from Socialist and Communist orthodoxies. But the pessimism of his childhood remains unshaken. The marvel indeed is that so sensitive and self-centred a nature should have escaped shipwreck. The thought of suicide, as is evident from the measured discussion in the closing pages of this book, cannot often have been out of mind. It is largely his strong sense of the reality of suffering and evil that makes this biography so arresting and impressive.

Liberation came to him, partly through friendships, still more through his own tough courage—a "Cornish tenacity" inherited through his father—but most of all through conversance with the arts. The effects on his mind of music, painting, sculpture, the Russian ballet, poetry, are traced in full detail in the fourth chapter ("Assimilation and Growth"), the longest and the most illuminating in the book. Mr. Bowyer's views on art are less coloured by emotional bias than many of his other reflections—the unbalanced diatribe against feminism, for example, in Chapter 6 or the extravagant denunciations, scattered up and down the volume, of educational and religious institutions. Yet even where he is most intolerant, there is something engaging in his candour. One of the most interesting passages is on his ideal of political and social reform, where he advocates an original type of State-Socialism, to be applied in the field of economic and material interests, with sedulous precautions against its intrusion into that of spiritual values.

The more philosophical portions of the book are, for the reason already stated, less satisfactory. They state speculative problems rather than answer them. The decisive influence on Mr. Bowyer's mind was that of Bergson, with whose doctrine of intuition he is naturally in sympathy, while dissenting from the narrow role allowed to intellect. His final verdict is for a dualism, naked and unashamed, between matter and spirit, the former being regarded as the source of evil, the latter as creative of eternal values, truth, beauty and goodness, "the greatest of which is Charity". Like T. H. Huxley, he sees the cosmic process in irreconcilable enmity to the moral. But can Nature be branded as immoral without a lapse on our part into the 'pathetic fallacy'? The point, however, in Mr. Bowyer's dualism that most provokes questioning concerns the relationship of the good and evil principles. Reality, he tells us, lies in this relationship; beauty, for example, belongs "to the very flow and creative movement of reality". Is this because the spiritual values have their source in the human mind? If so, since man is integral to Nature, it looks as though the cosmic process generated, not merely its own condemnation, but also the means of its own redemption. Yet we are told that charity, the supreme value, is "in some way an ultimate principle of eternal reality", with a "worth independent of time and place", and as such presumably independent of all temporal process. If this be so, must not the final word lie with the absolute values, and not with the relative and transitory forces of evil? Mr. Bowyer's noble faith in charity, and also in a Universal Mind with which the human mind is absorbed at death, seem to point the way towards a religious *Weltanschauung*, within which Nature as a principle of evil appears as an abstraction. Having gone thus far, Mr. Bowyer, whose whole life-history is a revolt against the abstract, has set himself a problem, the solution of which can only be reached by going still farther.

The author shows himself throughout intensely alive to the cultural influence, not only of his contemporaries, but also of the past. We note, however, a few errors, which do not seriously impair the value of his book. Has any Christian theologian ever thought of the Second Person of the Trinity as "existing before and after as well as during His incarnation, in the same human shape" (p. 33)? Calvin was not a Swiss (p. 80), but a native of Picardy. The Church Catechism does not suggest that everyone should be kept "in the state of life to which it had pleased God to call him" (p. 114); it says "shall please", which is very different. Nor is it true to say (p. 220) that Aquinas's philosophy was based "upon first principles about God", which were "merely affirmed". St. Thomas held that the knowledge of God's existence and of certain of His attributes was demonstrable by natural reason. Finally (*note*, p. 123) it was surely Lord Randolph Churchill, not Lord Palmerston, who "could never understand those damned dots".

W. G. DE BURGH.

MAN'S PRESENT AND FUTURE

The Outlook for Homo Sapiens

An Unemotional Statement of the Things that are Happening to him Now, and of the Immediate Possibilities Confronting Him. By H. G. Wells. (An amalgamation and modernization of two books—"The Fate of Homo Sapiens" and "The New World Order", published severally in 1939 and 1940. Pp. 287. (London: Secker and Warburg, Ltd., 1942.) 8*s*. 6*d*. net.

THE present volume is an amalgamation of two earlier books, "The Fate of Homo Sapiens" (1939) and "The New World Order" (1940). It will be remembered that in the earlier book Mr. Wells stressed the need for some contemporary movement similar to that of the French Encyclopædists of the eighteenth century, so that the human species, now dangerously out of harmony with its environment, might be enabled to make the necessary mental readjustments. He wants a campaign for "a re-invigorated and modernised education", primarily scientific in character.

"The scientific vision of life in the universe and no other has to be his vision of the universe. Any other leads ultimately to disaster. And since the existing educational organisation of the world does not provide anything like that vision nor establis the necessary conceptions of right conduct that ari out of it, it needs to be recast quite as much and ev more than the political framework. This will alm certainly involve such a kultur-kampf as the w has never seen before."

This new education will not stand by itself but be part of a new organization of human life inv ing "outright world-socialism scientifically pla and directed, *plus* a sustained insistence upon law based on a fuller, more jealously conc restatement of the personal Rights of Man". marizing his programme, Mr. Wells speaks of triangle of collectivisation, law and knowledg

Mr. Wells makes short work of current ideol and religions. "There is no creed, no way of li left in the world at all, that really meets the n of the time." He even seems somewhat dub about the Division for the Social and Internati Relations of Science recently created by the Br Association, and says that two divergent tende display themselves in it.

"One is plainly to organise and implement common creative impulse in the scientific min as to make it a vital factor in public opinion; the other is to restrain any such development of an authoritative and perhaps embarrassing criticism of the conduct of public affairs and to keep the man of science modestly to his present subordination."

Mr. Wells is of the opinion that great possibilities await scientific research if his new and stirring education increased the numbers of workers available. "I throw out the suggestion that in our present-day world, of all the brains capable of great and masterful contributions to 'scientific' thought and achievement, not one in a thousand, not one in a score of thousands, ever gets born into such conditions as to realise its opportunities. And of the millions who would make good, useful, eager secondary research workers and explorers, not one in a million is utilised."

Mr. Wells writes with a strong sense of urgency. For the better part of his life this prolific and ingenious writer has been one of the foremost of our propagandists for an outlook which is at the same time scientific and humane. It has now become a question how far the scientific outlook is *necessarily* bound up with humane and liberal ideals, and perhaps Mr. Wells is too ready to take such a connexion for granted. For this reason it is perhaps a pity that Mr. Wells is so impatient of the traditional religions, for, though in the past they may have been, and may sometimes still be, obstacles to progress, yet they too are capable of leading men to make "mental readjustments" of a desirable kind. To take one example. According to the Hindu view of life, when a man has reached a certain age and fulfilled certain responsibilities, he should retire from active life and devote himself to the contemplation of the ultimate mysteries. Mr. Wells might consider this a waste of time; but by banishing all the men of sixty from active life it would ease the situation of those surplus and frustrated young men whose existence Mr. Wells regards as the chief cause of wars.

J. C. HARDWICK.

GENETICS APPLIED

New Paths in Genetics

y Prof. J. B. S. Haldane. Pp. 206. (London: orge Allen and Unwin, Ltd., 1941.) 7*s*. 6*d*. net.

the thirty-three years that have elapsed since Bateson wrote his "Principles", two kinds of y have developed from that book. The one en concerned with digging the foundations of s. deeper and the other with building a ructure of more immediate utility. One has an integration with the physiology and ics of the chromosomes and of the cell; the leading, by a more laborious process, to an tion with plant breeding in general and with problems in embryology, biochemistry and ne.

ar as plant breeding goes, the first attempts ld on the Batesonian foundation were partly ointing. That was bound to be so because in nal genetics of Bateson the chromosomes are as symbols obeying deductively the estab- laws of the subject. Unfortunately, the easiest ements as well as the greatest difficulties in breeding depend on the chromosomes dis- g these laws. Moreover, the statistical instru- for handling plant breeding, even so far as the laws held, were not at first available, and have not yet been systematically applied.

In other directions, however, Bateson's formulæ hold well enough for practical purposes, and it has been possible ever since 1909 to go ahead with elucidating their applications to the problems which other branches of biology are continually putting in our way. In this work Prof. Haldane has played a foremost part. Nor could anyone else have played a similar part. He has been responsible for bringing together the organic chemist and the geneticist in the work of discovering how the genes co-operate in producing plant pigments. He has likewise brought together genetic analysis and the study of abnormal development. He has also, with Fisher, developed a statistical instrument not only for making good the experimental shortcomings of human breeding but also for establishing medical genetics as a discipline of independent value and validity.

This work Haldane has briefly summarized in the present volume. The paths he maps are inevitably far apart from one another, and few readers will be equally interested in the different techniques he describes. Perhaps he might have done more to spread the interest by sparing or explaining his words. For they are, I imagine, the most impressive in strength and variety ever brought together in a volume of this size. But the general reader need not be deterred by these technical expressions, for they can mostly be replaced by symbols without loss to the argument; and in their present context the mathematical equations can be taken as a decoration.

Some readers may feel that if Haldane is approaching his problems in terms of formal genetics he is thereby missing important possibilities of deeper analysis. I do not think he is missing much. A danger lies merely in formal concepts being supposed to have an analytical finality. Two examples of possible misconception may be taken from this book. In *Drosophila melanogaster* and *Zea Mays* it is said "almost every gene has been located" (p. 17). By this is meant analytically "every gene-difference so far detected by experiment". The method of experimental breeding cannot be said to have located every gene since every gene has not necessarily mutated and some genes are not individually detectable. Again (p. 108) it is inferred that "the normal allelomorphs of *W* and *f* control different unit processes", since the abnormal allelomorphs upset the control of these processes. This does not necessarily follow. It is a possibility. In the case of his amorphs, hypomorphs and hypermorphs, Muller has proved that the possibility may be realized. But in the case of other types of mutation he has equally proved that it is not and cannot be realized; which is *a priori* fairly obvious. The gene indeed as it exists in Nature is physiologically a somewhat informal body capable of breaking most physiological rules. The possibilities of rule-breaking that it is not likely to take advantage of are the mechanical ones such as those envisaged by Haldane (p. 110), of its running loose in the cytoplasm. That would be an offence against Nature since the reproductive cycle of the nuclear gene is naturally conditioned by its nuclear environment.

These objections like the others are no hindrance to Haldane's underlying argument. That argument is, in brief, that genetical analysis provides the key to problems in other fields which will baffle the wits and waste the labour of those who attempt to get along without it.

C. D. DARLINGTON.

FOOD PRODUCTION AND NUTRITION

By N. W. PIRIE
Rothamsted Experimental Station

UNDER the general title "Food Production and Distribution in Relation to Nutritional Needs", the recently established Nutrition Society held a meeting on February 28. Papers were read by Sir John Orr on "The Agricultural Implications of a Food Policy based on Nutritional Needs", by Dr. N. C. Wright on "Rival Claims of Animals and Man for Food", by Mr. E. T. Halnan on "Animals as Food Converters" and by Sir John Russell on "Planning for Agricultural Production". Each paper was followed by discussion, but the subjects of the papers were so closely interlocked that there was considerable overlapping of the points made by the twenty-five contributors to the discussion.

After two and a half years of war there is no evidence of a worsening in our nutritional state. Sir John Orr pointed out that, although there are differences between the feeding standards adopted in different countries and by different authorities, these are differences in detail and, broadly speaking, there is now unanimity. At the outbreak of war, both in Great Britain and in the United States, one third of the population fell below this standard ; a decade before that the proportion had been one half. This improvement gives us some cause for satisfaction, but it is clear that in planning post-war nutrition it is insufficient to aim merely at the restoration of the pre-war state. The consumption of foods such as milk might well be increased by 100 per cent in Great Britain, and our agriculture should concentrate on the production of perishable protective foods. In many parts of the Empire, for example India, the need is not confined to special foods, for the nutritional condition is appalling, and more of almost every sort of food is needed.

Both during the War and after it is not sufficient merely to consider which crops should be grown ; research is needed on the more efficient utilization of existing crops and on their improvement. Sir John mentioned, as an example of the former, the possibility of extracting edible protein from grass, "an idea started two or three thousand years ago under royal patronage", and as examples of the latter the production of vegetables richer than usual in minerals and of oats and wheat with an enhanced vitamin B_1 content. The main point brought out in the discussion was the need to ensure that the vitamins originally present in foods such as vegetables are not lost because of the delays in retailing or because of carelessness in cooking. Dr. S. W. Swindells spoke of the "planned destruction of vitamin C in canteen cooking" and referred to cases in which incipient scurvy, caused by this cooking, had been mistaken for pyorrhea.

Dr. Wright showed, in a number of different ways, that in pre-war farming in Great Britain animals were predominant ; for example, the population weighs approximately two million tons and the live-stock five, three million acres were devoted to the direct production of human food and twenty-seven to the production of food for animals, besides which the latter ate two thirds of the imports. This state of affairs has come about because most people prefer the flavour and small bulk of foods derived from animals, and in peace-time there is no real competition between man and animals ; for we get the better parts of the foodstuffs, whether imported or home-grown, and the animals use up the rest. In war-time this luxury cannot be afforded, for animals rarely have an overall efficiency of more than 25 per cent in the conversion of feeding-stuffs into human food.

The productivity of land devoted to the grazing animal is also low : an acre will yield six million calories in the form of potatoes, or three million in the form of wheat but only one million as milk and 200,000 as meat. The ploughing up of three million acres of grass, 15 per cent of the total, must therefore be accepted as a wise policy and it should be remembered that it amounts only to restoring the agricultural balance that existed in Great Britain sixty years ago. The best land was generally ploughed ; the policy therefore led to the loss of about a quarter of the stock-feed produced by grassland. This, together with the restricted importation of feeding-stuffs, has reduced the available fodder to one half. In these circumstances Dr. Wright has argued that it would be unwise to divert any more cattle food into human feeding by increasing the percentage extraction of flour. The raising of the extraction rate from 70 to 75 per cent has reduced the supply of wheat by-products by 400,000 tons and a further rise to 85 per cent will reduce it by 1,000,000. This fascinating, controversial and extremely complicated subject was not, however, argued in any detail at this meeting.

The question of efficiency of conversion of feeding-stuffs into human food was discussed by Mr. E. T. Halnan, Mr. A. N. Duckham, Dr. D. J. Ewing, Dr. J. Hammond, Prof. J. R. Marrack and Prof. D. M. S. Watson. A simple percentage efficiency rarely expresses the matter adequately because many animals can use feeding-stuffs that could, in no circumstances, be used by man. Even when efficiency is considered in terms of protein only, it should be borne in mind that animal proteins are of higher biological value than some of the plant proteins from which they are made. Young pigs and poultry are the only converters that need a type of food substantially similar to that needed by man. Egg production is as efficient as, or more efficient than milk production and some of the concentrates a present reserved for the dairy cow might well released for poultry feeding so long as this foo used primarily for eggs and not for table birds. the allocation of feeding-stuffs more attention s be paid to individual variations between an In general, the young animal is a more e retainer of protein and the old a more e retainer of calories, laid down in the form Since protein is the primary deficiency in th time diet, this would suggest that animals sh slaughtered young, but it can be argued on th side that the adult pig or ox may be eating f which there is otherwise no use. So long, th as they are not allowed to compete with with the, at first sight, younger and more e producers, there is no objection to their reten producers of fat.

Having considered, at some length, the q of the animal's efficiency, the meeting turn brief consideration of our own. Dr. Marrack cr the inefficient distribution of milk and point that there are fines for selling milk of low fat c but not for selling milk rich in bacteria or vitamin A. The lack of any preventive medic the farm and the great losses of feeding-stuffs, caused by the prevalence of mastitis and contagious abortion, were stressed by Dr. W. R. Wooldridge. Individual farmers in the same area may get widely different yields with the same crop. Dr. W. K. Slater asked how great the increase in our productivity would be if every farmer were as skilful as the best farmers, but no one was prepared to answer the question.

The various conflicting interests that have conditioned agricultural policy in the past were considered by Sir John Russell. In the first place the cheapest type of farming in Great Britain would be extensive ranching with few workers and much processing; for, except on a strip up the east coast, our best crops are grass and trees. The essence of planning is that we should decide what is wanted and then guarantee the farmer a market for that crop, otherwise he naturally tends to play for safety and farm in the cheapest way possible. Mr. Halnan had said earlier that the conversion of Great Britain into a "dormitory and exercise ground for animals" is sound economics when imported fodder is cheap, and Dr. F. Yates had explained how a labour shortage tends to encourage stock-feeding. Under planned agriculture half our food should be home-grown, but this does not mean that half of each particular food should be; there should be a great extension in milk and vegetable production. This would mean a decline in home production of wheat, butter and other commodities that keep well and so can be easily transported from abroad. It was noteworthy that the policy of increasing the wheat acreage, except as a purely war-time measure, found no support from any speaker at the meeting; instead there was substantial unanimity that Great Britain should adopt a policy somewhat similar to the peacetime policy of Denmark.

In summing up the results of the meeting, Sir Joseph Barcroft pointed out that, whereas a Government committee consists of men who have been carefully selected for reasons not always connected with their scientific attainment, it was open to anyone with knowledge to have his views heard at meetings such as this. He suggested that a channel should be established through which any agreed plan of action could be brought to the attention of the Government. The speakers who had urged on those responsible for the planning of diet the need for making that diet appetizing had his wholehearted agreement. The Society presumably claims no particular originality for this point of view, an earlier authority having remarked:

> Now, good digestion wait on appetite,
> And health on both!

UNITED STATES ANTARCTIC EXPEDITION, 1939–41

A SYMPOSIUM on the scientific results obtained by the United States Antarctic Expedition, 1939–41, was arranged by the American Philosophical Society at Philadelphia on November 21 last.

Prof. F. Alton Wade, professor of geology, Miami University, and senior scientist of the U.S. Antarctic Service, gave an introductory paper, in which he stated that one of the primary purposes of the Expedition was to carry on a comprehensive programme of scientific observations and research. A great portion of the programme was carried to completion by the twenty-one members of the scientific staff; due to an unexpected termination of the expedition, some phases were only partially completed. Detailed observations were made and programmes of research were conducted in the following fields: auroral phenomena, bacteriology, botany, cosmic rays, glaciology, magnetism, medicine, meteorology, micropalæontology, ornithology, petrography and petrology, physiography, physiology, radio, seismology, structural geology and zoology. Among the reports in preparation are the following: observations and height determinations of the aurora australis; the physiographical features of the Ross Shelf ice; the geology of the Weddell coast of Palmer Peninsula south of 68° S.; the geological features and formations in the vicinity of East Base; the sedimentary rocks of the Edsel Ford Mountains; the petrography and structure of the Rockefeller Mountains; ornithology report, which will include observations of bird life at both bases, at the Melchior Islands and along the ships' routes; the petrography and structure of the Melchior Islands; a correlation of radio receiving and transmitting conditions with magnetic phenomena and auroral displays.

Paul A. Siple, of the U.S. Antarctic Service, said that geographical exploration was carried on from West Base in 1940 by means of five reconnaissance field parties and two aircraft. The routes used followed but extended considerably beyond those opened first by the Byrd Expeditions of 1929 and 1934. The field parties' operations were limited to the hinter-coastal mountains east of Little America from long. 164° W. to long. 136° W. The parties were occupied mainly with surveying, geology, biology and meteorology. Aerial reconnaissance and surveying extended eastward to long. 120° W., including the major land features to nearly 200 miles south of the coast. This was accomplished by six flights, making more than a thousand usable aerial survey photographs available of the area.

Exploration to the west of Little America included three major flights over previously explored portions of the Ross Ice Shelf, crossing in each case into meridians of east longitude in the vicinity of lat. 78° 30′; 79° 20′; 81°; 83°; and 84°. Four newly discovered areas of internal disturbance were studied and fifteen bays and inlets were photographed in the continuous aerial survey of about four hundred miles of Barrier face from an altitude of 7,000 ft.

Southern exploratory operations were confined mainly to filling in the gap of mountains in the Austral Cordillera between Beardmore and Live Glaciers. However, the character of land formations east of the 120th meridian west indicated that there is no sea-level connexion between the Ross and Weddell Seas.

Other geographical accomplishments included glacial studies of the formation and physiography of shelf ice, problems of human adaptation to the climate of Antarctica, and studies of the cooling power of the wind.

An account of the geology of the large ranges around Little America was given by Lawrence A. Warner, of Johns Hopkins University.

The physical aspects of shelf ice were described by Prof. Alton Wade. The first detailed investigations of shelf ice were made at West Base during 1940. Included in the programme were the following: the variation of the density of the firn with depth, subsurface temperature measurements to a depth of 41 m., variations in the snow surface-level over a period of eleven months, horizontal and vertical movements within the firn, variations in the size of the constituent grains in various zones, stratification and horizontal banding. The results, presented in tabular and graphic forms, were compared with those obtained from investigations of the physical aspects of other types of glaciers; namely, valley glaciers and the Greenland Ice Cap. The lack of summer melt-water in the Ross Shelf ice eliminates what had been considered the most important factor in the process of firnification. However, without the aid of melt-water, the process does proceed with much the same results. An explanation of the firnification process in regions where the air temperature seldom rises above freezing was advanced.

Herbert G. Dorsey, jun., of the U.S. Weather Bureau, described some of the meteorological work. The programme at the East Base included the establishment of a completely equipped weather outpost more than a mile above sea-level on the plateau of Palmer Peninsula, Antarctica. Early in August 1940 a sledging party from East Base found a route to the plateau, making an ascent which previous explorers considered inaccessible to dog teams, and indicating the possibility of erecting a mountain weather station. Late in October, nearly 1½ tons of equipment were transported by four dog teams to the proposed meteorological outpost, located at 68° 7′ S., 66° 30′ W. on a plateau knoll about 12 miles east of the main base. Lester Lherke and Robert Palmer occupied the plateau weather station during November and December.

Despite prevailing north-easterly storms of drifting snow, Messrs. Lherke and Palmer spent their time between living quarters in a sturdy tent and a meteorological 'office' in a snow cave. For the first time in south polar regions, detailed high-level weather data were obtained in a form suitable for comparison with nearby sea-level observations.

Six-hourly check readings on all data were taken concurrently with those at East Base, in addition to the continuous autographic records of wind, pressure and temperature. Snow accretion and ablation were measured. Pilot balloon observations of the winds aloft were especially valuable when there was a low overcast below the plateau.

The mountain station was in contact with the base twice daily by low-power radio, sending coded weather reports which were included in the East Base weather transmissions to South America. These data, and frequent special reports, were helpful in forecasting for aviation operations at East Base and provide interesting material for future research on the meteorological phenomena of Palmer Peninsula.

A preliminary report on the magnetic and seismic programme was given by Roy G. Fitzsimmons, of the U.S. Antarctic Service and the Carnegie Institution of Washington. During the period April 27, 1940–January 21, 1941, a LaCour insensitive magnetograph was in operation at Little America. Variations of the declination and the horizontal and vertical components of the earth's magnetic field were recorded. Control observations were made with a magnetometer and a dip circle. A general description of the magnetic observatory and the method of observation as well as a report on the preliminary magnetic results were given. During the period November 17–December 28, 1940, a McComb-Romberg seismograph was in operation at the Rockefeller Mountains. A report of the earthquakes recorded and analyses of them were given.

Prof. S. A. Korff, assistant professor of physics, New York University, discussed the cosmic ray programme, which was planned with the view of throwing further light on the connexions between cosmic rays and meteorology, and also on the effects produced by such high-energy rays passing through matter. The first part of the programme involved the operation of two meters at West Base throughout the antarctic winter and a correlation of the records obtained there with temperature, pressure and other effects such as magnetic variation; and also the operation of the instrument on board ship to obtain further data regarding the temperature coefficient and the latitude-variation. Finally, aeroplane flights to high altitudes were carried out, which were to be studied in connexion with *radio sonde* data. The second part, namely, studying the effects produced by the radiation, involved (*a*) operating a cosmic ray counter on shipboard for comparison with the electroscope data, (*b*) the operation of a neutron counter, and (*c*) measurement of all bursts in the cosmic ray intensity on the long-term records.

With respect to the first part, a pressure coefficient was determined from the data at West Base for each 15-day period of operation. It was found that the least-square solutions of the correlation between pressure and cosmic ray intensity gave a slope (pressure coefficient) and an intercept (the extrapolation of the cosmic ray intensity to zero pressure) both of which varied over somewhat wider limits than were anticipated. Further analysis showed that this variation was associated with changes in the height of the mesotron-producing layer, but that contrary to the usual procedure in temperature latitudes, this could not be represented as an external temperature effect. This was found to be due to the fact that the surface temperature was not a good indicator of the distribution of the atmosphere in the column of air above the instrument. Using the *radio sonde* data, a new dependence upon upper atmosphere conditions was computed, and better agreement was obtained. This was checked by the runs made on shipboard in zones of different surface temperatures. The reduction of the observations was partly supported by a grant from the Penrose Fund of the American Philosophical Society.

A report by Arnold Court, of the U.S. Weather Bureau, dealt with the complete disappearance of the tropopause during the antarctic winter. This was revealed by the 190 *radio sonde* observations made during April 25, 1940–January 15, 1941, as part of the U.S. Weather Bureau's share in the scientific programme of the Expedition.

Summer-time observations show a definite and rather warm (−50° C.) tropopause around 9 km., above which the stratosphere is −40° C. or warmer. Spring and autumn soundings clearly show the transition from the winter type, with no clearly defined stratosphere, and with temperatures to −80° C., to the summer condition. This hitherto unsuspected behaviour of the upper air apparently is due to seasonal differences in radiation, but no indications of such conditions have so far been reported in the northern hemisphere, despite daily soundings at Barrow, Nome, Fairbanks, and other Alaskan stations, and intensive work in the U.S.S.R. and Scandinavia. None of these stations, however, is so close to the pole as Little America III (800 miles).

Another phase of the meteorological programme, the making of 230 pilot balloon ascents, revealed the prevailing summer-time wind at high levels to be south-west or west-south-west, not north-west as had previously been assumed. On the surface, observations covering an entire year were obtained, eleven months of them on a complete 4-a-day basis. Barograms were obtained in duplicate for the entire time, and thermograms except when winter cold stopped clocks. Complete wind records minute by minute were obtained from April 10 to camp abandonment on February 1.

Ernest E. Lockhart, of the Massachusetts Institute of Technology, described physiological investigations which were undertaken. An attack on the problem of acclimatization by white men in the antarctic was made by studying the effect of sudden changes in temperature on blood pressure, heart-rate and respiration-rate. This work was extended with data on 'normal' body temperature, blood pressure, heart- and respiration-rates and metabolism under basal conditions. A study of blood sugar levels was also made. Although pulse pressure is not effected significantly, systolic and diastolic pressures increase 25–35 per cent when a sudden change in temperature is the stimulus. Both the respiration-rate and the heart-rate are decreased somewhat. Under 'normal' basal conditions, pulse and respiration-rates, blood pressure and body temperature are slightly lower than normals recorded in temperate climates. Basal metabolism averages 10–15 per cent lower than that reported for temperate climates. Blood sugar levels, on the other hand, are slightly above the normal limit of 120 mgm. per cent.

Although the results presented should be extended, those now at hand indicate that acclimatization does take place in white men when subjected to the extreme conditions prevalent in the antarctic. It is suggested that the acclimatization process is begun by the continual pressor action of the low temperature. This primary stimulus, when repeated frequently, as is this case, induces hypo-effects in the several endocrine systems principally involved in metabolism.

Other papers were by Herwil F. Bryant, of the National Research Laboratory, Anacosita Station, Washington, D.C., on biological problems at East Base, J. E. Perkins, of the U.S. Biological Survey, on the biology of the West Base region, and Richard H. Black, of the U.S. Department of the Interior, on operations in Palmer Land.

CRYSTALLOGRAPHY AND PLANT VIRUSES

By F. C. BAWDEN

Rothamsted Experimental Station

Of the many techniques introduced into research on viruses during recent years, none has aroused more interest than those of the crystallographer. The value of these techniques in such work is amply shown by three recent papers* by Prof. J. D. Bernal and Dr. I. Fankuchen. The authors describe these papers as "only a preliminary and rough survey" and state that "many more years of work will be needed before exact and reliable interpretations can be expected". No doubt this is true. Nevertheless, what has already been done has greatly widened our understanding of viruses, in addition to bringing to light unsuspected properties of colloidal aggregates.

Before 1936 it was tacitly assumed that all viruses were incompressible spheres, and all calculations of their sizes were made on this basis. A cursory examination of the optical properties of purified preparations of tobacco mosaic virus was sufficient to show that this assumption was invalid and that the virus particles were anisodimensional. X-ray analysis soon showed that they were rods at least ten times as long as they were wide. Their width was found to be 152 A., but their length was too great to be measured by X-rays, although by means of specially designed cameras, spacings greater than 1000 A. were measured. Later work on sedimentation and diffusion constants, viscosity and with the electron miscroscope have all confirmed the size and shape first indicated by crystallographic studies.

One of the most interesting properties of solutions of tobacco mosaic virus of sufficient purity and concentration is their separation into two liquid layers, the separation occurring at increased dilutions with increasing purity. The denser phase is also the more pure. It is formed by the fusion of tactoids, and the suggestion offered by Prof. Bernal and Dr. Fankuchen that the cusps of the tactoids are occupied by particles of impurities explains many of the observed phenomena.

X-ray measurements have been made on dried preparations of tobacco mosaic virus and on solutions of varying concentrations. The pattern obtained falls into two parts: one of large spacings obtained with cameras working at very low angles, and the other of smaller spacings obtained with high-angle photographs. The first part of the pattern varies, the spacings depending on the *p*H and concentration. At the same *p*H, the spacings increase with increasing dilution, and at a constant concentration they decrease as the *p*H approaches the iso-electric point. Variations in the amount of water separating the virus particles are clearly responsible for these differences.

These patterns give us information on the effective size of the virus particles and also reveal previously unsuspected regularities in the structure of solutions. They show that the distance between the rods is inversely proportional to the square root of the concentration by volume, and that the particles are distributed in a hexagonal array so as to fill the available space as uniformly as possible. This regularity of packing of the long virus particles is typical of all orientated purified preparations, whether as fluid, gels or as the crystal-like needles produced by precipitation with acid or salts. In all states the particles are equidistant and parallel, but there is no evidence of any regular arrangement in the direction of the length of the rods. This is in striking contrast with the condition inside the infected plant, where true crystals with a three-dimensional regularity occur, and confirms other evidence that the processes of purification alter the viruses, probably by causing them to aggregate end-to-end.

The high-angle photographs give us our main information on the internal structure of the virus particles; surprisingly enough, the clearest have been given by orientated solutions of tobacco mosaic virus. The patterns from these photographs show that the particles have an internal regularity similar to that of crystals. Thus the virus preparations are in a sense doubly crystalline, for the components of the particles, in addition to the particles themselves, are regularly arranged. Their structure is more complicated than the anisotropic protein myosin but less so than pepsin. There is a spacing along the length of the particle of 11 A., and the virus seems to be composed of piles of sub-molecules with dimensions of 11 A. cubes. The spacings in the high-angle photographs are independent of the water content of the preparation, showing that even in solution the particles contain no appreciable amount of water. It is their internal regularity, lack of water and chemical simplicity that separate the viruses most sharply from the simplest recognized organisms.

---

* 1. "Introduction and Preparation of Specimens"; 2. "Modes of Aggregation of the Virus Particles"; 3. "X-Ray and Crystallographic Studies of Plant Virus Preparations", *J. Gen. Physiol.*, 25, 111–65 (1941).

Most of the work has been done with tobacco mosaic or closely related viruses, but some photographs have been taken of potato virus *X* and tomato bushy stunt virus. The last has spherical particles and crystallizes as rhombic dodecahedra, from which patterns were obtained with both high- and low-angle photographs. Each virus gives its own distinct pattern, and differences were even detected between related strains of the same virus, but the different viruses resemble each other more than any other type of proteins yet examined by X-rays. The differences found are of the order to be expected from a knowledge of the chemical, serological and physico-chemical properties of the viruses examined.

It is obvious that this work has opened up a field of research that promises to be extremely fertile. In virus research these techniques will be limited in their application by the difficulties of preparing most viruses, because of their small concentration in the host and their instability, in a form suitable for crystallographic studies. But with the extension of X-ray analysis to spacings as great as 1000 A. and the improvements in the electron microscope, particles of all sizes from bacteria to atoms become capable of direct examination, and a serious gap in our techniques for the examination of colloidal particles has been filled.

OBITUARIES

Captain T. A. Joyce, O.B.E.

THOMAS ATHOL JOYCE, who died at Hoveton, Norfolk, on January 3, was born in 1878, and was the eldest son of Thomas Heath Joyce, editor of the *Graphic* and the *Daily Graphic*. He was educated at Dulwich and Hertford College, Oxford, where he took his degree in 1901 and then studied Egyptology. He entered the British Museum as an assistant keeper in the Department of British and Medieval Antiquities and Ethnography under the keepership of Mr. (later Sir) C. Hercules Read. From the first he specialized in anthropology and was the first Museum officer to give his full time to the Ethnographical Collections including the American antiquities. He introduced considerable rearrangements in the Ethnographical Gallery, and prepared the greater part of the first "Handbook to the Ethnographical Collections", published in 1910 (second edition, 1925), which was essentially a condensed text-book of ethnology, liberally illustrated by specimens in the Museum. Thus he may be said to have laid the foundations of an Ethnographical Department as a distinct entity, destined, one may hope, to take ultimate shape as an independent Museum.

Joyce's attention was at first devoted principally to Africa, and by collaborating with the late Mr. Emil Torday, he secured for the Museum a splendid and well-documented collection from certain tribes of the Belgian Congo, principally the Bushongo, which surpasses both in quantity and quality any other single collection from the African continent in the Museum. Together with Torday he prepared two important monographs of these tribes, "Les Bushongo" (1910) and "Les Basonge, etc." (1922), published in the *Annals* of the Musée du Congo Belge. Afterwards his chief interest shifted to the archæology of Central and South America, where it remained for the rest of his life. These studies were stimulated by his friendship with Sir Clements Markham and Dr. Alfred P. Maudslay, and resulted in a series of authoritative text-books: "South American Archæology", "Mexican Archæology", and "Central American Archæology", which appeared in quick succession in 1912, 1914 and 1916. These were pioneer books, which for the first time presented to the student and general reader in a handy and condensed form a great mass of archæological data, hitherto scattered in a variety of monographs in different languages and not easily accessible. Although no longer wholly up to date, they remain standard works of reference, and have not been superseded.

During the War of 1914–18 Joyce's services were transferred to the War Office, where he became hon. lieutenant attached to the General Staff in 1916, and captain in 1917, receiving the O.B.E. in 1918.

After the War, and following on Read's retirement in 1921, he became deputy-keeper of the new Department of Ceramics and Ethnography, and reorganized the ethnographical section. He arranged for the transfer of the magnificent Maudslay Collection of Maya plaster-casts from the Victoria and Albert Museum, and for their exhibition in a special room in the British Museum, while he prepared the official "Guide to the Maudslay Collection of Maya Sculptures from Central America", published in 1923 (second edition, 1938). Of a more popular character was his "Maya and Mexican Art" (*Studio*, 1927), a most informative and attractively illustrated volume.

Joyce had always wanted to do field work, but the opportunity was late in coming to him. However, during 1926–1931, he organized a succession of expeditions to British Honduras on behalf of the Museum, four of which he led in person. These produced a rich harvest of finds, particularly from the "Old Empire" sites of Lubaantun and Pusilhá, including a number of inscribed stone stelæ and a large series of pottery whistle figurines of a new type. Illustrated reports of these expeditions were published in the *Journal of the Royal Anthropological Institute*.

Ever since 1902 Joyce had been closely associated with the activities of this Institute, of which he was honorary secretary and editor during 1903–1913, vice-president, 1913–17 and 1923–25, and president, 1931–33. Throughout this period he devoted much time and energy to furthering the aims of the Institute, attended its meetings, and was a frequent contributor of original articles and reviews to its *Journal* and to *Man*. He took an active part in organizing the exhibition of "Indigenous American Art" at the Burlington Fine Arts Club in 1920, the catalogue for which was prepared by him.

He was president of Section H of the British Association in 1934, his address taking the form of an original piece of research into the origins of yerba maté or 'Paraguayan tea'. He contributed articles to the "Encyclopædia Britannica" and to a number of more popular serials such as Harmsworth's "Universal History of the World" and Hammerton's "Wonders of the Past", as well as to certain foreign scientific journals. He was honorary secretary of the Hakluyt Society in 1923. In 1938, at the age of sixty, he retired from the British Museum owing to ill-health.

In spite of his erudition in his chosen subjects of ethnology and American archæology, Joyce carried his learning lightly, and his work was infused with an unaffected gaiety. Possessed of a happy and sociable temperament, and a ready wit, he never wearied of introducing students or visitors to his favourite subjects, or of trying to inspire in them a genuine interest in the collections under his charge; his influence led to a number of important benefactions, and was felt indirectly in many ways. As a foremost authority on all aspects of American archæology he leaves no immediate successor in Great Britain.

It was with sincere sorrow that his many friends noted, during his latter years, the signs of failing health in a constitution never very robust. But while illness inevitably led to the curtailment of his scientific work, it never succeeded in quenching the indomitable cheerfulness of his spirit.

He is survived by Mrs. Joyce, herself a leading authority on the Latin American countries, though perhaps better known to the public under her maiden name of L. E. Elliott. He had three children by an earlier marriage. H. J. BRAUNHOLTZ.

WE regret to announce the following deaths:

Sir William Bragg, O.M., K.B.E., F.R.S., director of the Royal Institution of Great Britain, and, during 1935–40, president of the Royal Society, on March 12, aged seventy-nine.

Prof. Lawrence J. Henderson, professor of chemistry in Harvard University, foreign secretary of the U.S. National Academy of Sciences, aged sixty-three.

Dr. George Senter, formerly principal of Birkbeck College, University of London, on March 14, aged sixty-eight.

NEWS and VIEWS

India

THE announcement made by Mr. Churchill in the House of Commons on March 11 that definite proposals have been formulated, and are being submitted to the leaders of Indian thought, for terminating the state of political unrest in that great country, will be welcomed on all sides. The Government made a pronouncement in August 1940 of the general principles upon which British rule in India was proceeding, indicating that full Dominion status would be granted as soon as possible after the War, under a constitution to be framed by Indians and acceptable to the chief elements of Indian national life, subject to the protection of minorities and to the fulfilment of Imperial obligations to the native States. This promise did not satisfy certain classes of opinion, and there has been bitter controversy, notably between the Congress party and the Moslem League. Reference has been made in NATURE on several occasions to the difficulties of the situation, and a noteworthy and constructive article on the subject by Sir Denys Bray, formerly Foreign Secretary, Government of India, appeared in NATURE of September 13, 1941, p. 301.

Mr. Churchill has now stated that the War Cabinet has agreed upon certain "conclusions for present and future action", based upon the general declaration already referred to, and Sir Stafford Cripps has volunteered to take these proposals to India. There he will strive to obtain the necessary assent to them from the chief parties of the country. In view of the grave turn taken by the War in the Far East, Sir Stafford will also consult with the Viceroy and Commander-in-Chief regarding the relation of these proposals to the defence of the country. The intervention of the War Cabinet at this critical juncture is a measure of the importance attached to the promotion of unity of purpose and action in India, and the outcome of Sir Stafford Cripps's mission will be awaited with keen interest.

Wheatmeal Flour and Bread

SPEAKING in the House of Lords on March 11, Lord Woolton, Minister of Food, announced that in order to reduce the very considerable tonnage of shipping used for the import of wheat into Great Britain, the Government has decided to increase to 85 per cent the ratio of flour from wheat milled in the country. From March 23 millers will be prohibited, except under specific licence, from manufacturing any flour other than wheatmeal flour, or some authorized speciality brown flour. This increased milling ratio entails the diversion of some of the products of wheat from the feeding of livestock to use as human food. But the change has been timed to take place when, with the approach of summer, it will not be necessary for the Ministry of Agriculture to change, from now until the end of August, the scale of rations of purchased feeding-stuffs allowed to stock and poultry feeders.

In order to absorb the stocks of white flour, no miller, factor, or importer will be permitted to deliver any white flour to any person other than a licensed baker, and then only providing that three times the quantity of national wheatmeal is concurrently delivered. Further, bakers will be authorized when producing national wheatmeal bread to include up to 25 per cent of white flour with the national wheatmeal. From April 6 it will not be permissible, except under licence, to sell any white bread, and a similar order referring to the use of flour in any other item of food will come into effect on April 20. Lord Woolton said that, while complete uniformity in the production of wheatmeal flour and bread is not possible, he is satisfied that we shall get a good bread, good in substance, good in texture, and agreeable to the palate. The composition and nutritive value of wheatmeal and similar bread have frequently been discussed in NATURE; attention may be directed especially to articles in the issues of May 31, 1941 (p. 665) and August 23, 1941 (p. 219).

Mechanical Engineers in the Army

ONE of the recommendations of the Beveridge Committee on Skilled Men in the Services was for the formation of a Corps of Mechanical Engineers in the Army (see NATURE, March 7, p. 255). Replying to a question in the House of Commons on March 11, Mr. Duncan Sandys, Financial Secretary to the War Office, referred to this proposal to pool the mechanical engineering resources of the various Corps. He said that it has now been decided to bring together the greater part of the Army's engineering maintenance services and to form them into a new and separate Corps. The new Corps will be made up of three principal components: first, the entire engineering side of the R.A.O.C.; second, all the maintenance personnel of the R.A.S.C., with the exception of formation workshop platoons and independent companies; and third, a large part of the mechanical maintenance personnel of the Royal Engineers. These far-reaching measures of reorganization would entail not only extensive administrative changes but also large-scale transfers of personnel.

Nervous Shock in Peace and War

AT a Chadwick Public Lecture delivered on March 17, Dr. William A. Brend considered nervous shock in peace and war. 'Nervous shock' is the same whether it is called 'nervous shock', 'shell shock' or 'traumatic neurasthenia' or any other of its names. Evidence of nervous shock can be found in early records, for example, in the Book of Job. Shakespeare gives an astonishingly accurate picture of 'battle-shock' in Henry IV. The modern history of the disorder begins about the middle of the nineteenth century when numerous cases were attributed to railway accidents. Many cases were seen in the Army during the War of 1914–18, and after the War a committee of investigation reported that the term 'shell-shock' had been "a gross and costly misnomer" which had done much harm. The essential cause of nervous shock is fear, but the effect of fear is often increased by injudicious 'suggestion'. Physical injuries play no part in the production of the disorder. Civilians suffering from shock after air-raids are not entitled to compensation under the Personal Injuries Act. Reasons were given for thinking that this was a very wise decision of Parliament. The influence of temperament was briefly discussed.

The biological significance of fear as an instinct was then examined. Capacity to feel fear is part of our normal mental make-up, and of the defence mechanism of the species. Fear only becomes a matter of self-reproach (that is, cowardice) if it is uncontrolled. Man then sinks to the level of the brutes and sacrifices the benefit of his intelligence. The public health aspect of nervous shock arises from the fact that the affection differs from organic disease or injury in that medical men are not considered to have a monopoly of the knowledge concerning either the cause or the pathology or the proper treatment of the disorder. There is a definite public opinion on all these questions which expresses itself through the Press and influences Acts of Parliament, provision of treatment and claims for damages, etc., in courts of law acting through judges and juries. It is very important, therefore, that this public opinion should be based on accurate knowledge. There are reasons for thinking that this is not the case at present, and indeed that in certain directions encouragement is given to the development of the disorder. Increased understanding of the nature of the condition would accordingly help to reduce its incidence.

Physical Society Optical Group

THE inaugural meetings of the newly formed Optical Group of the Physical Society were held on March 6 at the Science Museum and the Imperial College, South Kensington. It is ten years ago since the Optical Society was merged with the Physical Society, and although in this period a good number of meetings have been devoted to optical subjects, there has been a widely expressed desire for the formation of a Group for discussions and lectures of a less exacting and critical character than those associated with papers intended as original contributions to science. A preliminary meeting was held in December 1941 at which a draft constitution was approved, the objects of the Group being the provision of opportunities for the meeting of those with optical interests, the promotion of research and education in optics (including the improvement of optical literature), and fostering public interest in this branch of science. The first business of the inaugural meeting was to adopt the Constitution, and to elect Dr. A. O. Rankine as chairman with Prof. L. C. Martin as honorary secretary. A representative committee consists of Instructor Capt. T. Y. Baker, Mr. R. J. Bracey, Mr. W. H. A. Fincham, Dr. V. G. W. Harrison, Mr. W. C. Hynd, Dr. H. Lowery, Capt. T. Martin, Mr. J. Perry and Mr. E. W. H. Selwyn.

The first lecture was delivered by Dr. W. M. Hampton (Messrs. Chance Bros. and Co., Ltd.) who took as his subject "Some Problems relating to Optical Glass", dealing especially with recent work on the effects of heat treatment on the optical properties of the medium. The meeting in the afternoon was devoted to a paper by Mr. R. J. Bracey describing "A Multi-purpose Collimator" and a discussion, opened by Mr. J. Perry, on "Thermal Effects on the Performance of Lens Systems". Both subjects provoked a good discussion in which valuable technical points were brought out. Upwards of fifty members attended a luncheon at which Profs. A. V. Hill and A. C. G. Egerton, secretaries of the Royal Society, were guests of the Physical Society. In proposing the toast "The Optical Group", Dr. Rankine said the membership already includes 127 names. He hopes that the formation of the Group will be of value in the scientific life of the country, and that where papers of optical interest are forthcoming they will in future be made available for discussion by its members. Exacting demands are being made upon the optical industry in Great Britain, and the new Group can do considerable service if it leads to increased co-operation among those whose duty and honour it is to be called upon to fulfil them.

Royal Microscopical Society (1839–1939)

THE recent publication of the presidential address delivered by J. E. Barnard before the Royal Microscopical Society (*J. Roy. Mic. Soc.*, 61, 1; 1941) in celebration of its centenary, and the republication in the same journal of the address given in 1895 by A. D. Michael (the president in that year) calls forcibly to mind the comparatively recent advent of the microscope particularly as applied to the variety of fields in which it is now so familiar. At the time of the foundation of this Society, microscopes were primitive and were generally regarded as playthings compared to the telescope, although Lister had already published his epoch-making paper on the achromatic objective. The paucity of microscopical research in Great Britain had, in fact, already been noted by Schleiden, a slur which the Society was to do much to remove. Under Prof. Owen as first president the Society flourished from the start, and the first number of the *Journal* was published in 1841. One of the main features of the early meetings, attended in the nature of things almost exclusively by amateurs, was apparently the rapid introduction of new types of microscopes and much enthusiasm over technical improvements upon old. Among the members of the time we may note such names as John Queckett, Michael Faraday, Thomas Bell, with Ehrenberg as the first honorary fellow. Throughout its life the Society has stimulated interest not only in improvement of instruments but also in perfection of microscopical technique. The use of Canada balsam had been described shortly before the foundation of the Society, but it was not until 1848 that the use of glycerine was noted by Warrington.

In its first fifty years the Society achieved much—the homogeneous immersion lens suggested by Stephenson and worked out by Abbe, the binocular microscope, the Society's standard screw for objectives, the mechanical substage and hundreds of other improvements large and small—and in its *Journal* were presented many epoch-making papers the authors of which are now almost forgotten but whose work has formed a sure foundation for modern studies. In more recent times the Society has become progressively professional. Among the outstanding features of these later years we may recall the controversy over Abbe's diffraction theory of microscopic vision, with E. M. Nelson and J. W. Gordon as the more notable figures and calling to mind such great names as Sylvanus Thompson and Lord Rayleigh, a topic which has arisen from time to time during ensuing years, culminating in 1928, when it was generally agreed that under the conditions of illumination commonly employed the theory is no longer tenable. In 1902 Siedentopf introduced the ultra-microscope and in the following year the first paper appeared on ultra-violet light microscopy, marking perhaps the most important advance during the present century. The basis for the modern standard of procedure in microscopy was laid by Nelson in 1910 in a description of his method of "critical microscopy". Since that time, perhaps one of the more notable advances with which the Society has been connected is the improvement in design and the use of the polarizing microscope figuring so largely in current microscopy. It is confidently to be expected that in the future the Society will continue to serve microscopy with the same success as in the past. (See also NATURE, 144, 850; 1939.)

The Australian Anthropological Association

IN 1939 the Australian Anthropological Association was formed after discussion between the Anthropological Associations of New South Wales, Victoria and South Australia at the meeting of the Australian and New Zealand Association for the Advancement of Science held in Canberra that year. The headquarters of the new Association are to be situated in rotation for a period of two years in each State of the Commonwealth in which there is an anthropological society affiliated with the Association. During the first two years of its existence the headquarters of the Association were in Adelaide. Now they are at Sydney and will remain there until October 1, 1943, when they will be transferred to Melbourne. The official organ of the Association is *Mankind* which is the official journal of the Anthropological Society of South Australia. Officers of the Association are as follows: *President*, Prof. A. P. Elkin; *Vice-president*, Mr. F. L. S. Bell; *Hon. Secretary-Treasurer*, Mr. G. W. Watkins ("Hansard" Staff, Parliamentary House, Sydney).

Early Civil Engineering in France

IN a paper read to the Newcomen Society on March 11 entitled "The French Civil Engineers of the Eighteenth Century", Mr. S. B. Hamilton gave an account of the Corps des Ponts et Chaussées, founded in 1716, and of the school established in 1747 in connexion with it. The Corps was responsible for the main roads, canals, bridges, etc., of the country, and it has had many distinguished men on its staff. These men, such as Gautier, Frézier, Perronet, Gauthey, Chezy and Prony, possessed high scientific attainments, and in their memoirs and textbooks they established many of the principles underlying constructional work. When Telford looked for the literature of civil engineering, it was to France he turned, and his collection of books was bequeathed to the Institution of Civil Engineers. The outstanding man of the eighteenth century was Perronet (1708–94), who entered the Corps in 1745 and became director of the École des Ponts et Chaussées in 1747. His bridges, said Mr. Hamilton, were remarkable for boldness of design. Moreover, in an age of corruption, he set his face against the patronage which ruined some civil administrations; he selected his subordinates strictly on the grounds of ability and character.

Indian Journal of Genetics and Plant Breeding

THE formation of the Indian Society of Genetics and Plant Breeding at New Delhi in January 1942 has been quickly followed by the publication of the *Indian Journal of Genetics and Plant Breeding*. This journal is edited by Dr. B. P. Pal, Imperial Agricultural Research Institute, New Delhi, on behalf of the executive council of the Society. This welcome addition to genetical publications provides a valuable outlet and source of reference for the ever-increasing work of the research institutes of India. The volume for 1941 consists of one part, but in the succeeding years it is intended to publish twice a year.

In the first volume there are articles on hybrid vigour in rice by K. Ramiah and K. Ramasamy, chlorophyll deficiencies in rice by B. S. Kadam, colchicine induction of polyploids in *Capsicum annuum* by B. P. Pal, S. Ramanujam and A. S. Joshi, cytology of sterile *Sesamum orientale* by L. S. S. Kumar and A. Abraham and vernalization of Indian crop plants by B. P. Pal and G. Suryanarayana Murty. The Agricultural Commissioner with the Government of India, Dr. W. Burns, in the first paper of the publication, points out the great opportunities for plant genetics and plant breeding in India and welcomes the advent of the Society and *Journal*.

Smithsonian Institution Activities

THE report of the Secretary of the Smithsonian Institution and the financial report of the Executive Committee of the Board of Regents for the year ended June 30, 1941, includes a summary of the year's activities and reports on the United States National Museum, the Bureau of American Ethnology, the International Exchange Service, the National Zoological Park, the Astrophysical Observatory, the Division of Radiation and Organisms and other activities (Washington: Gov. Printing Office. 25 cents). The Smithsonian Institution has already been assigned a number of defence problems. The revision of all solar-constant values collected by the Astrophysical Laboratory from all Smithsonian observing stations from 1923 to the present is nearing completion and publication is expected to commence in 1942. A promising method has been developed of following the sun's variation by observations limited to the blue-violet region of the spectrum.

The Division of Radiation and Organisms has continued its studies on the relation of radiation to various phases of plant growth, and much information has been acquired on the respiration of etiolated barley seedlings. In addition to improvements in the performance of the spectrograph used in measuring carbon dioxide for very short periods, the spectral effectiveness of radiation for the growth inhibition of the oat mesocotyl has been further studied, as well as those of other species of grasses, and the ultra-violet irradiation of algæ. M. W. Stirling has made further archæological discoveries in southern Mexico in co-operation with the National Geographic Society, and Dr. Frank H. H. Roberts, jun., has completed his sixth and final expedition to the Lindenmuir site in northern Colorado, work which has added greatly to our knowledge of Folsom man and the early occupation of America. The work of the International Exchange Service was seriously hampered by world conditions, but scientific and other publications which cannot now be sent are being stored until the end of hostilities.

Meteorology in Art

MR. L. C. W. BONACINA's paper on the "Scenic Approach to Meteorology" (*Quart. J. Roy. Meteor. Soc.*, Oct., 1941), his fifth essay on the landscape-impression of weather, is a valuable contribution to that co-operation between science and art which is so important for the development of human personality. Truth and beauty, long kept in separate compartments of the mind, are now being welded together, a task in which Mr. Bonacina is a diligent and gifted worker. The papers of 1937–38 contain analyses of the paintings of Constable and Turner; that of 1939 carries on the subject to the treatment of landscape-meteorology by men of letters, and those of 1940–41 deal with the pictorial relation of atmosphere and the landscape background as seen by the author. In these descriptions there is a power of expression which enables the reader to share that faculty of observation with which the writer is endowed. Development of the æsthetic appreciation of Nature is especially valuable at the present time. At long last it is beginning to be realized that beauty should take an equal place with truth and goodness in that trinity of enduring values which is needed to fortify the mind during the stress and strain of war.

Rainbow Bridge over the Niagara Falls

THE approaching completion of the Rainbow Bridge at Niagara Falls, is a happy augury of that closer co-operation between the United States and Canada which has been intensified by the present state of world relations. The bridge was built under the auspices of an international body, the Niagara Falls Bridge Commission, consisting of eight members, four having been appointed by the Governor of New York and four by the Lieutenant-Governor of Ontario. The project has been financed by a bond issue of four million dollars.

The previous bridge at the same place, the correct name of which was the Falls View Bridge, was built in 1895. This was an arch structure which stood until January 27, 1938. On that day an ice jam which had formed in the gorge rose to an unprecedented height, and crushed the end portions of the arch ribs, causing a complete collapse of the bridge. The Falls View Bridge was the property of the International Railway Company, which after its destruction immediately prepared plans for a new structure. Public opinion, however, opposed the construction of another privately owned toll-bridge at this site and as a result the Company did not proceed with the plans for rebuilding. The Niagara River at the Bridge site flows through a gorge approximately 1,250 ft. wide and 180 ft. deep from the surface of the water to the top of the cliffs. The river is about 830 ft. wide and 175 ft. deep, and the flow is 25–30 m.p.h.

Demonstration of the Circulation by Experiment

IN a recent paper (*Isis*, 33, 443; 1941) entitled "The Significance of the Demonstration of the Harveyan Circulation by Experimental Tests" Dr. H. P. Bayon raises the question already put forward by Sarton in 1937 as to why the discovery of the circulation of the blood was completed by an English physician and why its acceptance was delayed until the middle of the seventeenth century. Galen's erroneous doctrine of the to-and-fro movement of the blood which was accepted for so long a period was based on the belief that the anatomical features of the heart, uterus and liver in the dog or pig must also be present in man. According to Dr. Bayon, the delay in the acceptance of Harvey's discovery of the circulation until the middle of the seventeenth century was due to the fact that it was not until then that accurate comparative anatomical observations became available through woodcuts, printed works and dissection. It was by the intelligent use of the experimental method that Harvey was able to test and control his interpretation of clinical observation and comparative anatomy. His investigations were completed by the discovery of the capillaries, which formed the missing link between the arteries and veins.

Golf Courses during War-time

VOL. 6 of the *Journal of the Board of Greenkeeping Research*, which has just been published, shows that the Research Station at Bingley is adapting itself most successfully to the new problems which are confronting golf clubs owing to the War. Land is being ploughed up on many courses, hay and silage crops are being taken from others and sheep-grazing is widespread. In consequence, the erection of adequate fencing has become a major problem. Trials are described which show that electrified fencing is likely to prove a simple and effective method of control, while at the same time it gives a cash saving of 80–90 per cent over the ordinary post and wire type. Methods for making silage from grass mowings have been investigated with very satisfactory results. Information is supplied as to how the grass can be collected, the type of silos to use and precisely how they should be filled. Young grass mowings are so nutritious that a really valuable contribution to the country's feeding-stuffs could be made in this way. If silage-making is not practicable, the grass mowings need not be wasted, but can be either composted for manure or dried for cattle feeding. An appeal is made to former subscribers for their continued support, as this is essential if the Research Station is to be in a position to fulfil its normal functions directly the War is over.

Certificate in Natural History

A new edition of the emergency regulations for the certificate of proficiency in natural history has just been issued by the University of London. The work, which has been specially designed to take advantage of the fact that large numbers of teachers are, owing to war conditions, presented with a unique opportunity of natural history study in the field, involves a directed course of private reading at home, attendance at a practical laboratory course of two weeks duration in the summer vacation, an approved plan of field-work suited to the student's locality to be written up in the form of an essay, and examination. Definite arrangements have not yet been made, but it is hoped that the practical course this year will be held at the Royal Holloway College, Englefield Green, Surrey, during July 26–August 8. Copies of the regulations and further information may be obtained from the University Extension Registrar, University of London, at Richmond College, Richmond, Surrey.

Diagrams and Formulæ for Lantern Slides

Prof. A. C. Chibnall, of the Imperial College of Science and Technology, London, has utilized 'Cellophane' and 'carbon' paper for the preparation, without photography, of lantern slides of line diagrams and chemical formulæ. Mr. J. W. Minnis, of the Chemistry Department, Heriot-Watt College, Edinburgh, states that he has obtained good results with two lantern-slide cover-glasses. A piece of typewriter 'carbon' paper is placed on one and the required diagrams or formulæ are drawn on the back of the 'carbon' paper, using a glass rod pulled to a point. The paper is removed, the second cover-glass placed over the carbon image, and the two glasses bound together in the usual manner. The resulting slide gave good reproduction in the lantern.

Synthetic Rubber Production in Canada

Mr. Howe, the Dominions Minister of Munitions, has announced the establishment of a Government-owned company called the Polymer Corporation, Ltd., with headquarters in Toronto, which will undertake the production in Canada of synthetic rubber of the Buna type. According to the Ottawa correspondent of *The Times*, Mr. Howe said that four plants would probably be required for the three stages of the manufacturing process to be employed. The output, when the plants are working at full capacity, is expected to be about 34,000 tons a year, but production cannot begin before the end of 1943. Colonel Arthur L. Bishop, a prominent Toronto industrialist, has been appointed president of the Corporation, and there are four other directors.

Announcements

Mr. R. A. Butler, president of the Board of Education, is to be chairman of the Scientific Advisory and Engineering Advisory Committees in succession to Lord Hankey.

Sir John Greenly was elected president for 1942–43 of the Institute of Metals at the annual general meeting held on March 11.

The Committee of the Athenæum has elected the following gentlemen, under the provisions of Rule II of the Club, which empowers the annual election by the Committee of a certain number of persons of distinguished eminence in science, literature, or the arts, or for their public services: Prof. P. M. S. Blackett, Langworthy professor of physics, University of Manchester; Mr. T. D. Kendrick, keeper of British and Mediæval Antiquities, British Museum; Mr. J. M. Keynes, economist, and fellow and bursar of King's College, Cambridge.

The following appointments in the Colonial Service have recently been made: S. R. Payne, assistant conservator of forests, Gold Coast; C. B. Garnett (senior agricultural officer, Zanzibar), senior agricultural officer, Nyasaland.

The conference on "European Agriculture: Scientific Problems in Post-war Reconstruction", arranged by the Division for the Social and International Relations of Science of the British Association, and postponed from March 13–14 owing to the death of Sir William Bragg, will be held on March 20–21 at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1, with sessions at 10.15 a.m. and 2.15 p.m. on each day as previously arranged, and the programme, so far as possible, unaltered. Fresh tickets will not be issued.

The Science Faculty of the Marx Memorial Library and Workers' School has arranged symposia on "Science and Technology in the Soviet Union" and the "Scientific Attitude to Fascism, with particular reference to Racial Theories", to be held at the London School of Hygiene and Tropical Medicine on April 5 and 6. Papers at the first symposium will include those by Prof. J. D. Bernal, Mr. Eric Godfrey, Dr. Norman Henry, Mrs. B. King, Dr. J. Needham, Mr. H. Rose, Dr. M. Ruhemann and Mr. H. P. Vowles. Those for the second symposium include the following authors: Prof. J. B. S. Haldane, Dr. C. F. D. Hawkes, Dr. P. Gorer, Prof. H. Levy, Dr. G. M. Morant and Mrs. Dona Torr. Further information can be obtained from the secretary, Faculty of Science, Marx House, Clerkenwell Green, London, E.C.1.

Errata. The May Lecture of the Institute of Metals is to be delivered on May 13, not May 31 as stated in Nature of March 14, p. 299.

In Nature of February 28, p. 243, under "Night Sky in March" the word "occultations" of the planets was inadvertently used for "conjunctions".

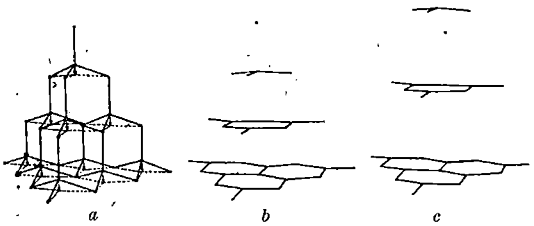
The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

A New Structure of Carbon

ATTENTION has been directed by Taylor and Laidler[1] to the appearance of 'extra' lines on X-ray photographs of graphite. These lines are given by several quite unrelated specimens and they do not seem to be connected with impurities. Finch and Wilman[2] and Taylor and Laidler[1] tried to interpret them as secondary diffraction phenomena of the graphite structure, but without producing any convincing evidence for their theories[3]. We find, however, that the lines may be explained by the presence of about 10 per cent of another structure that is closely related to graphite, and this therefore implies that carbon can exist in three different crystalline forms.

The new structure may be described in the following way. Ordinary graphite is composed of layers of carbon atoms arranged in hexagonal rings; these layers are so disposed that alternate atoms lie directly over other atoms and centres of hexagons respectively in the layer below. There are three different layers that can be built together to satisfy this condition; graphite uses two of them alternately; the new structure uses the three in sequence. Thus its unit cell has a c-axis $\frac{3}{2}$ times as long as that of ordinary graphite, in agreement with Finch and Wilman's observation that many of the lines may be indexed on the basis of the ordinary unit cell if the fractional l indexes $\frac{1}{3}$ and $\frac{2}{3}$ are allowed.

Although the structure may be referred to hexagonal axes, it is really rhombohedral, the basal symmetry plane of the graphite structure being replaced by centres of inversion, so that the alternating six-fold symmetry is lost. The simplest description of the structure is that it belongs to the space-group $R\bar{3}m$, ($a = 3{\cdot}635$ A., $\alpha = 39{\cdot}49°$) and has atoms at $\pm(\frac{1}{6}, \frac{1}{6}, \frac{1}{6})$.



a. Diamond ⟶ *α*-pseudo-graphite structure.
b. *α*-pseudo-graphite structure.
c. *β*-pseudo-graphite structure.

The structure, although closely resembling graphite, is similar to diamond in the arrangement of its planes; but in diamond the planes are puckered and closer together. Nath[4], in a theoretical study of the transition from diamond to graphite, has suggested that there is an intermediate structure formed, and it is interesting that this structure is exactly that described here. The accompanying figure is reproduced from his paper. It shows the diamond structure (*a*), an intermediate structure which has not been observed (*b*), and the new structure (*c*). There is, however, no explanation of the apparent existence in equilibrium of the two structures.

The experimental evidence on which we base these results will be described elsewhere.

We wish to thank Dr. Taylor for the loan of one of his photographs, and Mr. H. P. Rooksby of the General Electric Company for specimens of Ceylon and Bavarian graphites.

Purification of Penicillin

PENICILLIN has been obtained in the form of a highly purified barium salt by repeated fractional extraction from amyl acetate into water, chromatographic separation on an alumina column, treatment of the active fraction with aluminium amalgam and further repeated chromatographic separation until the alumina column appeared homogeneous. The preparation thus obtained, though not crystalline, has an activity of 450–500 Oxford penicillin units per mgm., corresponding to a complete inhibition of the growth of *Staphylococcus aureus* in broth in a dilution of 1 : 25,000,000. Penicillin must therefore be regarded as one of the most powerful antibacterial substances with predominantly bacteriostatic action known.

Details of the method of purification and an account of some chemical, physical and biological properties of penicillin will be published shortly.

Further Observations on the Increased Yield of Nucleic Acid from Irradiated Yeast*

DURING the course of investigations intended to extend previously reported observations[1] of increased yields of nucleic-acid-like substances from yeast irradiated with full ultra-violet radiation under conditions resulting in prolonged injury to the yeast cells, certain irregularities in the yields were noted. It now appears that these may be attributed to lack of quantitative yields in the final step of the chemical procedure wherein nucleic acid is precipitated.

As in the previous experiments[1], starch-free yeast (*S. cerevisiæ*, Fleishmann bakers' strain) was employed at a concentration of 300 gm. wet weight to each litre of suspension medium. Each suspension was divided into two equal portions. One was irradiated with full ultra-violet light from a quartz mercury arc. The other, which served as a control, was not irradiated but was subjected to the same conditions of stirring. Because of rise in temperature of the irradiated suspension above that of the control in certain of the experiments in which an air-cooled arc was used, a Kromayer water-cooled arc was substituted in other experiments. With it, the energy was insufficient to obtain an appreciable degree of killing (methylene blue test) during the period of irradiation (10–22 hr.). Subsequent to irradiation, nucleic acid was prepared from the control and irradiated suspensions by the method of Johnson and Harkins[2].

---

* Contribution No. 198 from the Department of Biology, Massachusetts Institute of Technology, Cambridge, Mass.

In all, six preparations were carried through chemically, but spectrographic data, forming the basis of this report, are available for only four of these. Table 1 shows the yields in terms of dry weights of the precipitates obtained by the Johnson and Harkins procedure. It will be noted that there was no correlation between the extent of injury and the yield of nucleic acid, and that in two of the four instances yields were actually much less from irradiated than from non-irradiated yeast. However, various irregularities in the final precipitations were noted; for example, the formation of suspensions of very fine particles in some instances (which were precipitated with difficulty) as contrasted with the formation of large, flocculent, easily precipitable particles in other instances. This suggested that an appreciable proportion of the nucleic acid might remain in solution in the supernatants after precipitation.

TABLE 1. WEIGHTS OF PRECIPITATES OBTAINED IN THE PREPARATION OF NUCLEIC ACID FROM IRRADIATED AND NON-IRRADIATED YEAST.

Preparation	U.V. Source	Suspensions medium	Time of irradiation, hr.	Extent of killing, per cent	Yield of nucleic acid per 100 gm. wet wt. of yeast	
					Non-irrad.	irrad.
5.2.41	Air-cooled	Reader's[3]	10	*ca.* 30	1·60 gm.	1·90gm.
7.17.41	Water-cooled	Reader's	22	negligible	1·73	1·83
7.23.41	Water-cooled	Isotonic saline	19	*ca.* 5	1·19	0·89
8.4.41	Water-cooled followed by air-cooled	Reader's	*ca.* 24	*ca.* 98	0·96	0·73

In order to determine whether this could account for the irregularities, ultra-violet absorption spectra were taken of the final supernatants from both irradiated and non-irradiated yeast. These showed, in every instance, the typical absorption spectra of nucleic acids (marked maximum near 2600 A., etc.)[4]. Quantitative determinations were then made of the amounts of nucleic acid (or nucleic-acid-like materials) remaining in the supernatants, employing the value 25·0 for the extinction coefficient of yeast nucleic acid in terms of gm. per litre concentration and cm. cell thickness[5]. The results of these determinations are shown in Table 2. These results indicate that in five instances out of eight, the amount of nucleic-acid-like material remaining in the supernatants was actually greater than that precipitated.

When the yields of the precipitates were added to the amounts remaining in the supernatants (Table 3), the total yields were in each instance greater for irradiated than for non-irradiated yeast. In the two instances (second and third preparations) in which the irradiation conditions were such as to result in only slightly lethal effects on the cells, the increased total yields were small. In the case of the 7.17 preparation, the total increase observed was within the limits of experimental error. In the case of the 8.4 preparation, however, in which the conditions were such as eventually to kill almost all of the cells, the total yield from irradiated yeast was almost twice that from non-irradiated yeast.

TABLE 2. NUCLEIC ACID REMAINING IN SUPERNATANTS AFTER REMOVAL OF PRECIPITATES, GM. PER 100 GM. MOIST YEAST.

Preparation	Non-irradiated	Irradiated
5.2.41	1·66	1·80
7.17.41	0·97	0·93
7.23.41	1·35	1·89
8.4.41	1·11	3·24

TABLE 3. TOTAL YIELDS OF NUCLEIC ACID IN PRECIPITATES AND SUPERNATANTS, GM. PER 100 GM. WET WEIGHT OF YEAST.

Preparation	Precipitate only			Total, precipitate and supernatant		
	Non-irradiated	Irradiated	Per cent increase or decrease	Non-irradiated	Irradiated	Per cent increase or decrease
5.2.41	1·60	1·90	+18·8	3·28	3·70	+13·5
7.17.41	1·73	1·83	+ 5·8	2·70	2·76	+ 2·2
7.23.41	1·19	0·89	−25·2	2·54	2·78	+ 9·4
8.4.41	0·96	0·73	−24·0	2·07	3·97	+91·8

These data demonstrated the lack of reliability of chemical precipitations alone in estimating the quantities of nucleic-acid-like substances present in various preparations. They show also the value of the spectrographic technique as a quantitative evaluation of the reliability of the chemical procedures.

Acute Inhibition of the Corpus Luteum Excited by the Onset of Anœstrus in Elephantulus

OVER several years we have accumulated extensive material of serially sectioned ovaries and uteri of *Elephantulus myurus jamesoni*. From an examination of the ovaries it is now possible to identify accurately the physiological state of the animal in respect of its menstrual or reproductive cycle.

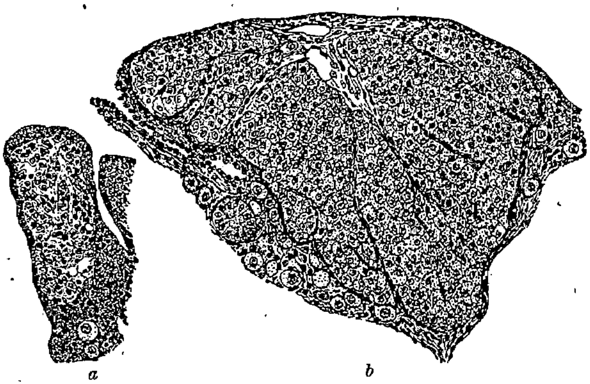
Elephantulus is a primitive mammal usually included among the Insectivora, but this mammal may turn out to be an important link between the Insectivores and the Primates.

Attention has already been directed to the extraordinary reactions shown in the ovary during ovulation[1] and in the uterus throughout the menstrual cycle[2]. In our most recent investigation we have correlated the post-ovulatory changes in the uterus with the structure of the corpus luteum[3].

Although not previously mentioned in our publications a third factor facilitates the identification of the stage in the cycle that an animal happens to be in after ovulation. This is the extent of decomposition of the numerous eggs[4] present in the uterus after ovulation.

Anœstrus in Elephantulus extends from March or April until the end of July or the beginning of August.

Recently in examining our series No. 428 of an animal killed in April 1939, we found that both the ovaries and uterus presented an appearance typical of anœstrus. To our surprise, however, we discovered degenerating eggs in the uterus. In an œstrous animal such eggs are normally associated with well-developed corpora lutea in the ovary and the stage of dense stroma in the uterus. On carefully re-examining the ovaries we discovered curious cellular bodies which were neither corpora lutea of the normal menstrual cycle nor corpora lutea of a remote or recent pregnancy (see accompanying illustrations).



TWO CORPORA LUTEA OF ELEPHANTULUS ASSOCIATED WITH EGGS IN THE UTERUS IN APPROXIMATELY THE SAME STAGE OF DEGENERATION.

(a) From an animal in early anœstrus; (b) from an animal in the menstrual cycle. (× 125.)

Obviously this animal ovulated just a little while before the precipitous onset of anœstrus inhibited the whole post-ovulatory process and the normal development of the corpora lutea.

From these facts we venture to conclude the following:

(a) Anœstrus inhibits the pituitary in respect of its gonadotropic hormones.

(b) The continued development of the menstrual corpus luteum after ovulation is dependent upon the presence of a gonadotropic hormone from the pituitary.

(c) This hormone maintaining lutein growth is acutely inhibited by the factor or factors responsible for anœstrus.

(d) The onset of anœstrus in any individual animal is a relatively acute process.

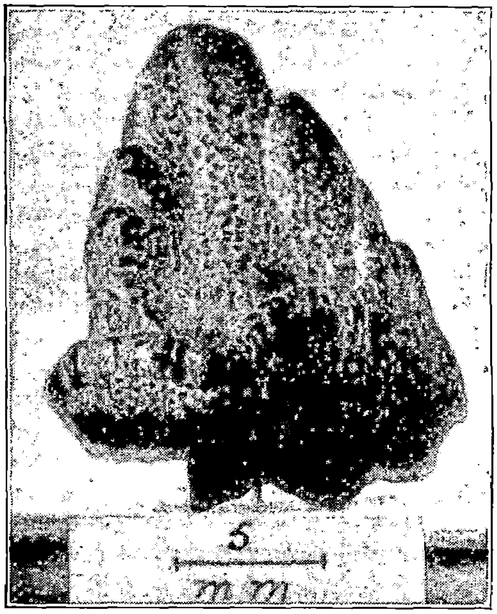
Anthracotheriidæ in Ceylon

IN 1941 a collection of fossils made by Mr. M. C. Wickremasekera from the Ratnapura beds near Kuruvita in Ceylon was sent to the Colombo Museum by Mr. D. N. Wadia, Government mineralogist. Examination revealed the premolar tooth of a member of the family Anthracotheriidæ of the order Ancodonta. Dr. E. H. Colbert, of the American Museum of Natural History, to whom sketches and photographs of the tooth were afterwards sent, agrees with my identification and this confirms a discovery of considerable importance to Ceylon geology. In the first article[1] describing mammalian fossils from Ceylon it was suggested that they were of late Pliocene or early Pleistocene age.

The subsequent discovery that remains of a race of the most recent member of the Proboscidea, namely, *Elephas maximus* Linné, occur with those of the hippopotamus, suggested that the Ceylon fossil beds are much younger, but the more advanced mineralization of the present discovery suggests that the age of these deposits dates back to the Pinjor or even farther. A feature of unusual interest is that in Ceylon fossils of anthracothere, hippopotamus, *Elephas maximus* and bovines occur in the gem-bearing bed which ranges in thickness between six inches and three feet, whereas in the Siwaliks the last of the Anthracotheriidæ occurs in association with the hippopotamus over a thickness of about seven thousand feet of fossiliferous beds, after which the hippopotamus survives alone in later beds which are about another three thousand feet thick. The Siwaliks are separated from Ceylon by nearly 25° of latitude and should the Ceylon tooth prove to belong to a local subspecies of *Merycopotamus dissimilis* (F. et C.) it will be of importance in correlating the fossil deposits of the Pinjor horizon of India, the Upper Irrawaddy beds of Burma, the Tji Djoelang horizon of Java, and the Ratnapura deposits of Ceylon.



The dimensions of the tooth are as follows: length of base 32 mm., width of base 18 mm., height above root 30 mm. The specimen was obtained from the debris at the mouth of a gem pit where the gem-bearing bed, which is usually also fossiliferous, lay at sixteen feet below the surface.

Nitzschia Cultures at Hull and at Plymouth

MORE than thirty years ago a persistent culture of a minute diatom was obtained by Allen and Nelson[1]; they refer to it as *Nitzschia closterium*, W. Sm., *forma minutissima*. This persistent culture has been maintained at Plymouth ever since, and has been distributed to many workers at home and abroad. The species has proved to be a useful food for many kinds of marine larvæ and a convenient diatom for experimental work. A sample was sent to Hull about 1930 and has been grown there until the present time. When first sent the great majority of the frustules, as at Plymouth, were of the straight or slightly curved fusiform shape characteristic of the species, but in 1932 a very few three-rayed or tri-radiate cells were present; their abundance was certainly much less than 1 per cent. In cultures derived from Plymouth stock such cells have been seen by other workers, notably by Barker[2]. By 1934 there had, at Hull, been a slight increase in the abundance of these tri-radiates and they may have formed as much as 1 per cent of the cultures. In 1936 the proportion had risen to more than 50 per cent. Thereafter the abundance of tri-radiates steadily increased so that by the spring of 1939 they comprised 97 per cent, and by the summer of 1941 more than 99 per cent, of the cultures.

The Plymouth stock cultures first passed into the care of one of us late in 1937, from which time two strains have been kept. In 1939, when attention was specially directed to them, well over 90 per cent of the frustules were tri-radiate, indeed in one strain the culture was almost entirely tri-radiate. By June 1941 both strains were about 99 per cent tri-radiate. In 1939 two clone cultures of normal cells and one clone culture of tri-radiates were established, a sample of the latter—as well as of one of the former—being sent to Hull in February 1940 and maintained there by sub-culturing. All clone cultures for long remained almost true to type: after the first few months a very few cells of the alternate kind were to be seen; lately, there have been some significant changes. At Plymouth one clone normal (the clone normal not sent to Hull) has become about 5 per cent tri-radiate, but the other clone normal at Plymouth and at Hull is still almost pure. It is, however, to the tri-radiate cultures that attention is here directed.

The two strains of Plymouth stock and the clone, all three about 99 per cent tri-radiate in the preceding June, had by November 1941 produced large numbers of normal cells. There is little doubt from the appearance of the cultures that this was done by the gradual reduction and eventual elimination of one ray of the tri-radiate, for of the remaining tri-radiates a large proportion had one ray reduced. Another process by which normals may derive from tri-radiates is known but does not appear to have played any part in this particular change-over. The very remarkable feature is that while these changes were taking place at Plymouth almost identical changes were occurring in the cultures at Hull: until a short time ago neither author was aware of this fact. Even the percentages are now closely similar, as the following table shows. It is based on sub-cultures made at the end of November 1941 and counted recently when dense.

	Percentage tri-radiate	
	June 1941	February 1942
Plymouth Stock 569	99·3	61·6
,, ,, 589	98·6	64·7
,, clone tri-radiate	98·8	60·3
Hull Standard Stock	>99·0	62·0
,, General ,,		64·5
,, clone tri-radiate		68·25

The almost parallel recent history of these cultures, grown so far apart and differently treated as to time and frequency of sub-culturing, lighting, temperature, etc., is so striking that we are anxious to hear from anyone who, in the past ten years, has kept cultures of this diatom, especially if their cultures be derived originally from Plymouth stock. It is hoped to include in a paper to be published later any relevant observations other workers may be able to contribute.

Occurrence of a Halophilic Alga in Mid-Cheshire

ON October 26, while conducting some preliminary investigations in the course of an ecological survey of a salt-spring situated at Aldersey[1], seven miles south-south-east of Chester, the filamentous alga *Percursaria percursa* (formerly known as *Enteromorpha percursa* (Ag.)) was encountered. The presence of this alga is interesting because Percursaria is usually found in rock pools on the shore between tide marks. The only previous record of Percursaria from a brackish non-coastal region, which has come to my notice, is that mentioned by Grove[2] from brackish waters in the Midlands. The alga was evidently found in a ditch near the canal at Salwarp, Worcestershire. A note of this find is recorded by West and Fritsch[3]. The species is described and figured by Newton[4].

Percursaria percursa occurs in large masses at the Aldersey spring and is spreading into a neighbouring brackish gutter. The spring water, at the time the specimen was collected, had a salinity of 1,675 parts per 100,000 and a *p*H value of 7·0 (Lovibond comparator).

I gratefully acknowledge the assistance of Dr. Helen Blackler, of the Liverpool Museum, and Mr. E. G. Williams, of Chester, for their independent identifications of the alga.

RESEARCH ITEMS

The Sargasso Sea

THE problem of the origin and extent of the weed in the Sargasso Sea, which has long been a debatable matter, is discussed by G. E. R. Deacon in a paper on the Sargasso Sea in the *Geographical Journal* of January. A century ago, Meyen argued that the weed grew as it drifted in the sea, that normal reproduction was vegetative and that the origin was in the Gulf of Mexico. Murray and Hjort did not subscribe to this theory; they believed that the weed would disappear if fresh supplies did not continually arrive from the coast. The weed certainly is not disappearing and there is not the least foundation for the statement of Tilden to that effect. It occurs in strips or patches, large and small, and is rarely out of sight in the whole area of the sea. Most of the weed belongs to two species, *Sargassum natans* and *S. fluitans*, but other forms are recognized. Mr. Deacon believes that there is little doubt that the weed is self-supporting, the total having been built up during centuries from plants drifted from the West Indies and by vegetative growth *in situ*. The annual contribution from the coasts is small. Evidence of vigorous vegetative growth, in leaves and branches free from Bryozoa, is abundant. Neither of the main forms, however, has been identified from the shores of the West Indies, but this does not preclude its original coastal origin. The absence of any field of weed on the coasts large enough to keep the Sargasso Sea as full as it is of weed shows that the weed must grow and multiply as it drifts, while the distribution of the currents is responsible for its accumulation and maintenance.

Excretion of Ammonia by Blowfly Larvæ

IN contrast with the vast majority of insects, which excrete the greater part of their nitrogenous waste in the form of uric acid and its salts, the larvæ of blowflies eliminate most of their waste nitrogen in the form of ammonia. This latter method of nitrogenous excretion results in a most economic procedure since it involves no loss of unburned carbon. Pamphlet No. 109 of the Council for Scientific and Industrial Research, Commonwealth of Australia, comprises two papers on the above subject by F. G. Lennox, the insect studied being *Lucilia cuprina*. In the first article, the rate and distribution of ammonia production form the main subject. It appears that practically all the ammonia produced in the mid-gut passes to the hind-gut via the Malpighian tubes. It does not reach its maximum until one or two days after the peak of larval growth. The second article is concerned with the enzymes responsible for ammonia production in the species named. Judging by the large quantity of ammonia liberated in the presence of adenosine, it is concluded that adenosine deaminase is probably an enzyme of major importance in blowfly larvæ. Deamination occurs chiefly in the midgut region where proteolysis can also be demonstrated. The few other insects known to excrete ammonia nitrogen include the larvæ of *L. sericata* (Hobson, 1931), and of *Calliphora vomitoria* (Wienland 1906). In order to establish the claim that the ammonia liberated by such larvæ is a product of their own metabolism and not of associated micro-organisms, the insects were reared from sterilized eggs in a sterile synthetic media. The details of the technique employed and the apparatus are fully described in the present pamphlet.

Rate of Growth and Timber Quality

L. P. V. JOHNSON, forest geneticist, National Research Laboratories, has reported the results of an examination of the effect of rate of growth upon timber quality carried out upon forty-three trees of hybrids and parents involving *Populus alba*, *P. grandidentata* and *P. tremuloides* (*Canadian J. Res.*, 20, 28; 1942). As these hybrids can usually be propagated readily by vegetative means and may have a rate of growth far in excess of their parents, the point is of great interest and the tentative conclusion—that rapid growth is not seriously detrimental to quality for paper pulp production—suggests great practical possibilities for these new hybrids. A short, thick habit of growth in these trees was found to be significantly correlated with high wood density, but correlation between growth-rate (in terms of annual increment of volume) and wood density was insignificant. In the same tree the fibres in wide annual rings were longer on the average than those in narrow rings—in the same annual ring the fibres of the early wood were shorter and thicker than those of the late wood. The last point recalls the observation of Priestley and Scott (*Proc. Leeds Phil. Soc.*, 3, 235; 1936) that the fibres among the vessels of the early wood of Fraxinus were shorter than those in the later wood.

Mechanism of Germination of Conidia of Erysiphe

THE mildews are characterized by a dispersal mechanism which seems to operate in relatively dry conditions and the conidia then seem to germinate and the infection to spread under low humidity conditions that would seem likely to militate against a mildew epidemic. Some very interesting observations and suggestions upon the subject appear in a paper by Harold J. Brodie and C. C. Neufeld of the Department of Botany, University of Manitoba (*Canadian J. Res.*, 20, 41; 1942). In *Erysiphe Polygoni* the conidium is cut off by a ring of wall material which forms from the periphery of the hypha inwards until a perforate disk is formed. Later, the pore in this disk is closed by a minute papilla by which alone the mature conidium remains attached until passively discharged. The wall of the conidium is relatively impermeable to water and stains enter only at the papillate end. This papilla thus seems to provide a permeable spot on the wall which is only exposed after detachment. The authors suggest that abstriction is thus followed by release of carbon dioxide and entry of oxygen through the papilla and that germination then starts even at low humidities. In support of this view they show that germination is checked in an atmosphere of nitrogen or in one containing 10 per cent carbon dioxide.

Volatile Reducing Substances in Vinegars

A STUDY of the volatile reducing substances in vinegar was reported by J. M. Whitmarsh to the Society of Public Analysts and Other Analytical Chemists on February 4. The Edwards and Nanji tests for oxidation and iodine values have been applied to a number of vinegars and the results compared with the results obtained by those authors. Estimations have been made of the amounts of various volatile reducing substances in vinegars and the presence of acetyl methyl carbinol in spirit vinegar has been demonstrated, contrary to several statements in the literature. The oxidation and iodine values of solutions of these volatile-reducing substances have been measured, and it is concluded that the distinctive values for spirit vinegar are due to its content of alcohol, and those for malt vinegar are due, largely if not entirely, to the presence of alcohol and acetyl methyl carbinol.

Equilibrium between Cuprous and Cupric Compounds

MANY cuprous compounds tend to decompose into cupric compounds and copper, and the chief controlling factor governing this instability has been shown by J. E. B. Randles (*J. Chem. Soc.*, 802; 1941) to be the degree of covalency or electrovalency of the bonding between the copper ions and neighbouring ions or molecules, which depends mainly on the polarizability of the latter. The transition from ionic to covalent type depends on a large decrease of ionic charge and so of electrostatic interaction. As the polarizability of the anions or molecules interacting with the copper ions increases, the interaction energy increases and the cuprous compound becomes more stable. The equilibrium between cuprous and cupric ions in presence of metallic copper was investigated with different compounds, and the results confirm the theoretical deductions.

Absorption Spectra of Unsaturated Ketones

THE absorption spectra of a number of β-unsaturated ketones have been examined by L. K. Evans and A. E. Gillam (*J. Chem. Soc.*, 815; 1941). Woodward (*J. Amer. Chem. Soc.*, **63**, 1123; 1941) has tabulated the wave-lengths of the absorption maxima of many ketones, and his data show that they fall into three classes according to the substitution of the C=C—C=O group, the locations of the intense absorption bands being as follows: monosubstitution (α or β), 2250 ± 50 A.; disubstitution (αβ or ββ), 2390 ± 50 A.; trisubstitution (αββ) ± 2540 ± 50A. The nature of the substitution of the chromophoric group in these compounds can thus be predicted from the location of the main absorption band. Evans and Gillam find that, with very few exceptions, this generalization is well obeyed, which increases the usefulness of absorption spectra in the elucidation of organic structure. The study of the effect of substituting simple αβ-unsaturated ketones with methyl groups showed that a larger bathochromic effect is produced by substitution on the β-carbon atom than by substitution on the α-carbon atom. Other types of compounds are also discussed in the paper.

Measurement of the Flow of Liquids and Gases

A USEFUL summary of methods used for measuring the flow of liquids and gases is given in a paper by E. Ower and the subsequent discussion (*Trans. Inst. Chem. Eng.*, 18, 87; 1940). The various types of instruments used are described and the methods of calculation discussed, and there is a short bibliography of recent literature.

Time Bases

O. S. PUCKLE, in a paper read before the Institution of Electrical Engineers on February 4, refers to the development of various types of time bases employing hard and soft valves, both for general- and special-purpose applications, the aim of the paper being to elucidate the principles involved rather than to describe the actual instruments in detail. Several little-known devices are described, and the highly important technique of producing and controlling pulses is considered. The results of recent investigations into some peculiarities of the gas-discharge triode are included, and presented in the form of an appendix.

Radial Velocity Curve of δ Cephei

INVESTIGATIONS of radial velocity curves of Cepheids have been published by Rufus and other Michigan observers, and these indicate the existence of marked relative displacements between spectral lines originating at different levels in the stellar atmosphere. These levels have been taken as equivalent to the heights of the same lines in the solar chromosphere. It is significant that Jacobsen and Mendenhall found no convincing evidence for the existence of relative displacements, and the same conclusion was reached by Petrie, who obtained about a hundred single-prism spectrograms of δ Cephei, using the same instrument as the earlier Michigan observers. H. A. Brück and H. E. Green have now discussed this subject (*Mon. Not. Roy. Astro. Soc.*, **101**, 8). They have made use of a number of four-prism spectrograms of δ Cephei which had been secured with the Newall 25-in. refractor of the Solar Physics Observatory, Cambridge, and which had been originally used for a spectrophotometric study of line intensities and their variations during the cycle. These spectrograms have a dispersion of 13 A./mm. near $H\gamma$ and are in good focus over a wave-length region extending from λ 4250 to λ 4650. The negative results of Petrie and Jacobsen were confirmed, no definite relative displacements between lines of different atmospheric levels being detected. It is possible that small differences between the velocity curves of groups of neutral iron and ionized titanium lines exist, and there is some evidence for relative shifts in the case of the neutral-calcium line λ 4425·6.

Solar Parallax and Mass of the Moon

THE Astronomer Royal has published a paper on "The Solar Parallax and the Mass of the Moon from Observations of Eros at the Opposition of 1931" (*Mon. Not. Roy. Astro. Soc.*, 101, 8); this is a summary of his complete results (*Mem. Roy. Astro. Soc.*, 66, Part 2). Independent determinations from observations of R.A. and Declination are in good agreement and the value adopted for the solar parallax is 8·7904″ ± 0·0010″. The probable error which has been assigned to the final value of the solar parallax is based on the high internal accordance of the results, and the question arises regarding a possible systematic source of error due to differential atmospheric dispersion. A discussion of this problem shows that the effects of colour differences between Eros and the reference stars tend to assume a random nature and the general effect is small. A description of the procedure adopted for the determination of the constant of the lunar equation is given, and the value derived from the Eros observations is 6·4390″ ± 0·0015″, and from this and the solar parallax the reciprocal of the mass of the moon is 81·271″ ± 0·021″. From this value and that of the constant of precession, 5493·156″, the computed value of the constant of nutation is 9·2266″ ± 0·0008″; this is much larger than the adopted value, 9·210″. An unexplained discordance has existed between the observed value of the constant of nutation and the value inferred from the observed values of the constant of precession and the mass of the moon, and it is remarkable that the new value of the mass of the moon has increased this discrepancy. It is highly desirable that an accurate value of the constant of nutation should be determined from observations specially planned for the purpose.

CHEMOTHERAPEUTICAL USE OF HALOGENIZED PHENOLS AS EXTERNAL DISINFECTANTS

By PROF. BERNHARD ZONDEK

Rothschild Hadassah University Hospital and Hormone Research Laboratory, Hebrew University, Jerusalem

FOLLOWING the detection of large quantities of œstrogenic hormone in pregnant mare urine[1], we have observed that mare urine remains for months without decomposing. Germs inoculated in long-standing urine did not multiply. The disinfecting action of horse urine is due to phenol bodies present in it (1 gm. per litre). Human urine contains 100–150 mgm. free phenol per litre urine and 150–250 mgm. combined phenol.

The fact that large quantities of phenol are eliminated in the urine encouraged us to study the chemotherapeutic use of the phenol bodies in human beings, in spite of the fact that Robert Koch and Paul Ehrlich had pointed out in their classical studies on this subject that no internal disinfection is possible by means of external disinfectants. Bechhold and Paul Ehrlich[2] ascribed the failure of this method to the fact that the halogenized phenols studied by them (tetra-bromo-*o*-cresol, hexa-bromo-di-oxy-diphenyl-carbinol, etc.), although not causing precipitation, developed only a limited activity in serum.

In the following a brief account is given of our investigations, as a result of which it became apparent that the external disinfectants—the halogenized phenols were studied—were able to effect internal disinfection. For therapeutic use a phenol body had to be chosen which, although harmless to the organism, would have a high disinfective potency. Most promising in this respect seemed a mono-halogen-phenol containing various methyl groups. Halogenized xylenol, a substance which has been employed for many decades as an external disinfectant[3], was found most suitable. It is also a halogenized xylenol that constitutes the basic principle of 'Dettol', which is much used in England as an effective disinfectant for the surgeon's hands as well as for the genital region in obstetrics[4].

In our experiments we used mostly *p*-chloro-xylenol (1, 3-methyl, 5-oxy, 2-chloro-benzene), briefly referred to here as *CX*. We also studied the chemotherapeutic action of several esters and ethers of *CX* (sodium sulphate ester, acetate ester, benzoate ester, ethyl ether, methyl ether). Furthermore, we examined *ortho-iso*-propyl-*CX* and *sec.-iso-amyl-CX*.

The disinfective action of *CX* *in vitro* was found to be 25–30 times as strong as phenol[5]. In several experiments we found that *CX* is able to destroy typhoid germs as well as proteus or *B. coli* in dilutions of 1 in 10,000 and staphylococci in dilutions of 1 in 20,000 within 60 minutes.

In contrast to the results of Paul Ehrlich's experiments, we found that *CX* exercises a protective effect *in vivo*. Although it was not possible to save mice infected with streptococci, the experiments gave positive results when rats were infected with pneumococci. It was only in some of these experiments that we succeeded in saving the rats from this deadly pneumococcal infection. Parallel experiments with sulphapyridine gave similar results.

A colorimetric method for the quantitative determination of *CX* in the urine and blood of animals and men was elaborated in co-operation with Dr. Benyamin Shapiro. This method will be described elsewhere.

An oily solution of 10 per cent *CX* was found most suitable for parenteral application in man. Good results were also obtained with a mixture of *CX* and *CX*-benzoate, 10 c.c. of which contained 2 gm. of the active substance. These preparations had to be injected deep intragluteally. The disadvantage of the parenteral route of administration is the occasional occurrence of painful infiltrations.

Following observation made in 1929[6], that œstrogenic hormone, which is also a phenol body, is absorbed by the skin, we have also studied the behaviour of halogenized phenol in this respect. The quantities of *CX* excreted during five days after injection of 1 gm. *CX* intramuscularly in a rabbit and after rubbing in 1 gm. *CX* in the form of an ointment on the shaved back of a rabbit were found to be the same, approximately 15 per cent. It thus follows that *CX* is absorbed through the skin, circulates in the blood and is excreted with the urine.

Percutaneous application in man in the form of a 30 per cent *CX* ointment never causes any secondary effects and may be given in large doses (10–20 gm. of the active substance a day). The following observations indicate that both the parenteral as well as the percutaneous application of *CX* in man has a chemotherapeutic effect:

(*a*) After administration of small doses the urine excreted remains sterile for many weeks. In this respect *CX* is more than seven times as active as sulphanilamide and six times as active as sulphapyridine. The total elimination of free *CX* amounts to 2–8 per cent, its excretion being greater in alkaline urine as compared with acid urine. It is thus advisable to give sodium bicarbonate and sodium lactate, before treatment with *CX*, so as to obtain an alkaline urine (*p*H 7·5–8·5). In human urine 31 per cent of the *CX* administered is eliminated in a combined form; 14 per cent is combined with glycuronic acid and 17 per cent with sulphuric acid.

(*b*) Twenty-four hours after inoculation of 5–50 staphylococci in 2 c.c. of defibrinated blood, 100–800 million staphylococci may be counted. When the blood of *CX*-treated patients is used for the same experiment, the multiplication of these organisms is hindered, making any count impossible; nevertheless, the organisms are not all destroyed, since on further passage of this blood to blood agar, staphylococci do grow. This powerful bacteriostatic effect is possible after the intramuscular or percutaneous application of only 2·5 gm. *CX*. So far as the bacteriostatic activity in the blood is concerned, the treatment with *CX* is far more effective than with sulphanilamide and more active than with sulphapyridine and sulphathiazole. The antibacterial action of *CX* in blood has so far been tested against staphylococci only.

(*c*) While organisms inoculated in the contents of cantharide blisters of normal men multiply rapidly, strong antibacterial effects are possessed by the same in *CX*-treated patients. This is an indication that *CX* penetrates the body tissues.

So far as the mechanism of action of *CX* is concerned, we found the following. Bouillon containing 100 mgm. *CX* per litre will destroy inoculated staphylococci. In order to obtain a similar effect with serum, 5–10 times higher doses of *CX* must be added. This is in conformity with Paul Ehrlich's experiments, in which serum was found to hinder the activity of halogenized phenols. From our experiments it is apparent that this inhibitory effect is due to proteins, since after addition of serum-protein to bouillon, higher amounts of *CX* were needed to inhibit the growth of bacteria, as compared with clear bouillon. After treatment with *CX*, it is the whole blood and not the serum that possesses antibacterial properties. We may thus conclude that *CX*, or a substance derived from it, attaches itself o the red blood corpuscles. The blood bactericidity of *CX*, which was examined in 500 cases, begins after 24 hours, at a time when no *CX*, or only a small amount of it, is present in the blood. We may thus assume that the active antibacterial substance is formed in the blood and is possibly not identical with *CX*. The bactericidal substance is bound to the red blood corpuscles since bactericidity disappeared once the erythrocytes hæmolized.

The clinical results obtained with *CX* will be reported in detail elsewhere. Here we may briefly note the following. The percutaneous application of 15 per cent *CX* ointment is an excellent means for he disinfection of the operative field, the skin remaining sterile for 12 hours. By the percutaneous application of 3 gm. *CX*, an antibacterial activity of he blood is simultaneously provoked, thus providing some protection against possible post-operative nfection. Since this anti-bacterial effect lasts for 24–48 hours, a further application of *CX* is advisable. The same is true of its use in obstetrics. In these cases at least 3 gm. of the active substance must be rubbed in the vulva, in order to combine the disinfection of the external genital organs with an antibacterial effect in the blood.

We have obtained most encouraging results in the treatment of urogenic infections (cystitis, pyelitis). Infections due to staphylococci and proteus react particularly well, and a disinfection of the urine is obtained. Infections due to *B. coli* react clinically well, that is, the symptoms disappear after a short time, but in most cases the *B. coli* are not destroyed, a bacteriostatic effect thus being obtained. The treatment lasts five days, the daily dose of *CX* amounts to 10–20 gm., which is given percutaneously with 1–2 gm. parenterally.

Up to now we have treated seven cases of puerperal septic infections. In two cases of streptococcal pyæmia, the treatment failed to give good results. In the other five cases the patients recovered. These ncluded two cases of staphylococcal pyæmia. In septic general infections the treatment—mostly percutaneous—should last at least fourteen days. Our experience in the treatment of other infectious diseases is still limited.

It should be especially emphasized that treatment with halogenized phenols in man is harmless and causes no secondary effects.

FOLK-LORE OF ERUPTIVE FEVERS

AT a meeting of the Section of the History of Medicine of the Royal Society of Medicine on February 4, Dr. J. D. Rolleston read a paper on the folk-lore of eruptive fevers, in which he said that during the last two Congresses of the International Society of the History of Medicine held at Madrid in 1935 and at Zagreb and Belgrade in 1938, medical folk-lore formed a considerable part of the proceedings. In contrast with some diseases, particularly whooping-cough, pulmonary tuberculosis, skin diseases, especially warts, and eye diseases, the folk-lore of the eruptive fevers is somewhat scanty.

The abundance of folk-lore connected with each exanthem appears to be directly related to the antiquity and importance of the disease, so that the amount of folk-lore of smallpox, measles, scarlet fever and chicken-pox is represented in the order named. There does not seem to be any folk-lore connected with German measles, which did not receive general recognition as an independent disease until after the International Congress of Medicine held in London in 1881.

As regards the causation of the acute eruptive fevers there do not appear to be any popular causes for their occurrence, such as catching colds, sexual excess, or punishment for an evil life, as in the case of pulmonary tuberculosis, skin diseases and venereal diseases. With the exception of smallpox, none of them has been assigned a divine origin. In accordance with medical folk-lore generally, prophylaxis was rarely employed in the acute exanthemata except smallpox. There were many examples of the same treatment being applied to the eruptive fevers generally, such as overheating the patient or flagellation with nettles with the object of bringing out the rash, the use of red blankets and bed-hangings and coprotherapy.

As regards the causation of smallpox, numerous examples were given by Sir James Frazer and others of outbreaks of smallpox in different parts of the world being attributed to a goddess or, much more rarely, to a god, and of the various means employed to win their favour or prevent their visitation. Examples were also given of the avoidance of calling the deity or the disease by its proper name and using instead some more or less euphemistic words or phrases. The supposed transfer of smallpox to animals, plants and inanimate objects in accordance with folk-lore practice in other diseases was also described. Prophylaxis of smallpox by inoculation was a folk-lore method carried out by old women in Turkey long before it was adopted by the medical profession in Great Britain and France. Besides overheating the patient, the folk-lore treatment of smallpox consisted mainly of animal and plant remedies and the invocation of patron saints.

There are more popular errors concerned with measles than with any of the other acute exanthemata, such as the belief that it is a trivial disease, that it cleans out the system and makes the child less liable to contract other diseases, and that patients should not be washed, owing to the delusion that such an act tended to drive the rash inwards. In none of the acute exanthemata is coprotherapy more frequently employed than in measles, especially in the early stage of the disease. There were several examples of the belief that measles could be best treated by transfer of the disease to animals and plants, and apart from any idea of transfer numerous folk-lore remedies were supplied by animals, plants and minerals.

Doubtless owing to scarlet fever having been isolated as an independent disease much later than smallpox or measles, its folk-lore is much less than that of the other two diseases. Popular errors connected with it included the view that the term 'scarlatina' meant a mild form of the disease, that second attacks did not occur, and that a mild attack could transmit only a mild attack to another person. Instances are occasionally met with in which scarlet fever was supposed to be transferred to animals, such as a dog, bear or sheep. Amulets were sometimes worn for prevention of the disease. There does not appear to be any patron saint connected with scarlet fever as in smallpox or measles.

Although chicken-pox is probably as old as smallpox, owing to its usually mild character and uncomplicated recovery very little folk-lore is connected with this exanthem, but it has had a large number of popular synonyms which are out of proportion to its real significance. The term 'chicken-pox' was first used in medical literature in 1694 by Richard Morton, who spoke of a form of smallpox "called in the vernacular the Chicken-Pox". Fuller also in 1730, in a paragraph in his "Exanthematologia", wrote: "I have adventur'd to think that this is that which among our women goeth by the name of Chicken-pox."

Another example of folk-lore anticipating scientific medicine is furnished by the fact recently mentioned by W. N. Pickles that the connexion between herpes zoster and chicken-pox was known at Aysgarth in Yorkshire long before this connexion was demonstrated by Bokay in 1892.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Friday, March 20—Saturday, March 21

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE (DIVISION FOR THE SOCIAL AND INTERNATIONAL RELATIONS OF SCIENCE) (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1).—Conference on "European Agriculture: Scientific Problems in Post-War Reconstruction".

Friday, March 20

10.15 a.m.—"Measures for Reconstruction". (Chairman: Sir John Russell, F.R.S.)

2.15 p.m.—"Economic and Kindred Problems". (Chairman: Mr. F. L. McDougall.)

Saturday, March 21

10.15 a.m.—"The Future Betterment of European Farming". (Chairman: Dr. A. J. Drexel Biddle.)

2.15 p.m.—(Chairman: Sir John Russell, F.R.S.)

Monday, March 23

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. H. P. Rooksby: "X-Ray Technique in the Industrial Laboratory". (Cantor Lecture, 2; Subsequent lecture on March 30.)

ROYAL GEOGRAPHICAL SOCIETY (in the Kinematograph Theatre of the Imperial Institute, Prince Consort Road, London, S.W.7), at 5 p.m.—Geographical Sound Films, by courtesy of the Belgian Government: "Nos Soldats d'Afrique"; "Musée du Congo Belge"; and "Sous l'étoile d'or", with commentary in French.

Tuesday, March 24

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir Lawrence Bragg, F.R.S.: "Metals", 4: "Strength and Flow of Metals".*

Wednesday, March 25

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Annual General Meeting. Prof. H. L. Hawkins, F.R.S.: "Some Episodes in the Geological History of the South of England" (Anniversary Address).

Thursday, March 26

INSTITUTION OF NAVAL ARCHITECTS (at the Royal Society of Art John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Eight third Annual Meeting. 3 p.m.—Sir Stanley V. Goodall, K.C.B. "Sir Charles Parsons and the Royal Navy" (Parsons Memori Lecture).

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), 2.30 p.m.—Sir Lawrence Bragg, F.R.S.: "Physicists after the War"

SOCIETY OF CHEMICAL INDUSTRY (FOOD GROUP) (JOINT MEETIN WITH THE BRISTOL SECTION) (in the Chemical Department, the Un versity, Bristol), at 6.30 p.m.—Prof. F. L. Engledow: "Science an the Land" (Jubilee Memorial Lecture).

Friday, March 27

INSTITUTION OF CHEMICAL ENGINEERS (at the Connaught Room Great Queen Street, London, W.C.2), at 11 a.m.: Twentieth Annu Corporate Meeting.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on before the dates mentioned:

PRINCIPAL OF THE TECHNICAL COLLEGE, COATBRIDGE—The Direct of Education, Lanarkshire House, 191 Ingram Street, Glasgow, C. (March 25).

DEPUTY SUPERINTENDENT, Telegraph Works, Calcutta, for duti as PRODUCTION ENGINEER FOR TOOL AND LIGHT MACHINE SHOPS—The Secretary, Central Register (Section D.261), Ministry of Labou and National Service, Queen Anne's Chambers, Westminster, Londo S.W.1 (March 28).

ASSISTANT IN THE NUTRITION DEPARTMENT—The Secretar Pharmaceutical Society of Great Britain, 17 Bloomsbury Squar London, W.C.1 (April 7).

ASSISTANT (MALE) TO THE PUBLIC ANALYST—The Secretary, Healt Department, Grey Friars, Leicester.

PROFESSOR OF CIVIL ENGINEERING AND DIRECTOR OF THE SCHOO OF ENGINEERING at Canterbury College, Christchurch, New Zealan —The Secretary, Universities Bureau of the British Empire, c University College, Gower Street, London, W.C.1.

LEADERSHIP IN WORLD RECONSTRUCTION

THE agreement which has recently been signed by the Governments of Jugoslavia and Greece, establishing a Balkan union, like the subsequent announcement that the Czechoslovak and Polish Governments in London had reached agreement on certain basic principles of the confederation to take place after the War, is a reminder that the shaping of the New Europe is already taking place. The extent to which these agreements, clearly regarded both as the nucleus of a wider federation and as steps towards the consolidation of fluid national structures and anarchic political and economic conditions, embody the principles enunciated in the Atlantic Charter, no less than the fact that they have been reached in London, is a token of an inevitable measure of Anglo-American leadership in the New Europe.

It is for this reason that the question of Great Britain's relation to Europe calls for such careful study at the present time. There is, moreover, a further reason, stressed by Mr. P. J. Noel-Baker in the recent debate on the War in the House of Commons. Among our other vital needs, he said, is a European Council or some new and better machinery of European collaboration, because of what might happen in 1942. If we are to deal a mortal blow at the Axis through one of its main weaknesses—its moral bankruptcy—we must make a tremendous effort at political education to show the enemy peoples that our victory is in their own true interests.

That effort involves a careful study of the relation of Great Britain, and indeed of the United States also, to Europe, and gives pertinence to the able analysis already prepared by the Reconstruction Committee of the Royal Institute of International Affairs. Much more indeed is involved. We cannot expect to achieve moral ascendancy and victory without setting our own house in order. There is a sense in which, as Dr. C. H. Gretton argues ably in his recent volume under that title, victory begins at home, and the moral basis of victory, overshadowed in most, though not in all discussions of war aims—Barbara Wootton's "End Social Inequality", in the Democratic Order series of pamphlets is a further example—may well prove to be the decisive factor in either a long or a short war. Decisive victory even over an unjust foe may be delayed until we have cast out our own social injustices and planned our national economy on a rational and just basis. Only the most superficial thinking can dismiss the examination of reconstruction as irrelevant to the mobilization of our full war effort, apart from the necessity of being prepared for the task of reconstruction after the War.

Granted the necessity of a moral basis for reconstruction and its value as a weapon in the supremely important political offensive, the great need, as Dr. J. A. Bowie points out in a Saltire Pamphlet*, is for factual knowledge. A clear picture of the problems involved is a first essential to further investigations, and the great value of the PEP broadsheet, "Britain and Europe", and the Democratic Order pamphlet, "Reconstruction and Peace", by "Balbus" *, and the programme outlined by the Reconstruction Committee of the Royal Institute of British Architects, lies in the contributions offered to that end. The objectives thus visualized and alternative lines of policy outlined lose none of their value by being based on such assumptions as the military defeat of Germany, the continued co-operation of the Dominions and of the United States after the War, and sufficient unity and steadiness in the public mind to permit the effective application of a consistent and reasonable policy.

---

* The Basis of Reconstruction. By Dr. J. A. Bowie. (Saltire Pamphlet No. 1.) Pp. 38. (Edinburgh and London : Oliver and Boyd, 1941.) 1s.

It is a common feature of all the pamphlets referred to above that they recognize the necessity of distinguishing between the measures to be adopted immediately after the Armistice and those more permanent measures or policies required later. To some extent they all also recognize that the purpose of Britain's European policy and her general conception of her relation to other European policy must be determined on the basis of the essential facts governing our relations to Europe—geographical situation and communications, population and social standards, industrial and economic potential, political ideas and institutions.

Short-term measures and long-term policy cannot be determined in complete separation, and the British and the American peoples must make an early decision as to whether or not they will accept their responsibilities for leadership in Europe. If an affirmative decision is to command the support that alone can make it effective and win the confidence of the European peoples, it must be based on a full survey of the situation. Moreover, the existing Inter-Allied Council is in itself a guarantee that the measures calling for immediate consideration or action immediately the War ends, such as the occupation of Germany or other territories, the economic and social needs of Europe, such as relief food supplies, prevention of disease, housing, the refugee problem, credit and currency measures, the establishment of orderly government and of civil and political rights wherever required on the Continent, will be dealt with in collaboration with other Governments and with regard for their contribution.

What is essential is that these immediate measures should not be framed without regard to the long-term problems. Here the governing question is that of our relations with Germany and the measures to be adopted to remove the risk of future German aggression. A sound choice between the two alternatives of a policy of co-operation designed to create among the German people a real interest in, and will towards, peace, and a policy of enforced subordination of Germany designed to remove her power to disturb the peace, must be based not alone on a study of the facts and of the implications of those alternatives, the risks implicit in them, the demands each policy would make on us, and the machinery of political co-operation required to give it effect. It must also be based on thinking in terms of Europe and of the role of the German people within the European whole. Only so can we avoid the dilemma of two irreconcilable propositions, which at first sight the German question appears to present.

It is in the long-term economic and social problems that the way of escape from the German dilemma appears to open before us, as is well shown by "Balbus". Here we must first seriously consider the possible choices: a return to the ideal of a great commercial republic, with the implication that the possibility of any country having an autonomous policy is severely limited, or an economy more or less planned to secure economic or social security. That again involves examination of such questions as the practicability of insulating national economy and of running a social security policy on a truly international basis. At this point we link up once more with the question of internal reconstruction, and of the extent to which effective British leadership is possible unless we can show definite domestic achievement in the field concerned.

These questions, indeed, rather than the form of the international machinery required, are the immediate live issues. Much of the machinery created for co-operation in war may serve equally well the immediate purposes of post-war relief, practical reconstruction and the planning of Europe's agricultural and industrial life. Out of the experience of such work, as Dr. Bowie suggests, may develop the political forms necessary to sustain and extend it. By such association for common ends, and the deliberate promotion of understanding of cultural and political values, will come faith and vision widely held, on which it will be possible to base such specific organizations as a European or world federation.

Much the same approach is found in the PEP broadsheet. There the task of building a European commonwealth is seen as consisting of two parallel processes. First, the establishment by Britain and the Allies of a permanent ascendancy over the aggressors, providing the framework of order and security within which the New Europe can begin to grow. Simultaneously with this is the second process of reconstructing and developing European life in the direction of a social and economic and cultural community, which all its citizens have a common interest in maintaining and furthering, and to which all of them, Germans and Italians as well as Danes, Dutchmen, Spaniards and the British, will come to feel a loyalty commensurate with their loyalty to their own countries. To give the New Europe the flesh and blood which alone can make it a living and lasting reality, the peacemakers must set out consciously and boldly to build a European community into which the national communities will slowly merge.

As to the measures by which such broad objectives are to be achieved, in the first stage the broadsheet visualizes a programme of first-aid relief with the necessary organizations, all plans for this emergency period being drawn up as integrated parts of a general

---

* Reconstruction and Peace: Needs and Opportunities. By "Balbus". (The Democratic Order, No. 10.) Pp. 64. (London: Kegan Paul and Co., Ltd., 1941.) 1s. net.

plan, related to a clearly formulated pattern of the future Europe. Both the planning and the execution of the programme should be put in the hands of a unified authority or European reconstruction commission, created with wide autonomous powers for the purpose and not left to independent action by the British or any other Government. The second stage will be the development of a new, more coherent, economic and social system in Europe. On the economic side, the system must be directed to the welfare of the peoples of Europe and the progressive raising of their standards of living, and the use of Europe's resources for that purpose should be planned for Europe as a whole and for five- or ten-year periods at a time, not on a year-to-year basis.

On the social side the problem of restoring order out of the disintegration following the collapse of Nazism and Fascism will be urgent, and out of the emergency institutions improvised may grow new social forms of lasting value in European life. Indeed, the key to the restoration of social stability may well be the rebuilding and development into new forms of those cultural and other institutions which are the life-blood of a free community, but which have been persecuted or suppressed in totalitarian Germany—the universities, churches, trade unions, professional organizations, the free Press and the radio. It is here that the long experience of the British people of the value of these institutions in the life of the community gives them such a great opportunity for moral leadership, and, while in the early stages British, Dominion and American personnel are bound to play a leading part in the development of individual leaders, the contribution of the free peoples already represented in Great Britain, whether as émigrés or as refugees from the Nazi tyranny in Europe, will be of the utmost importance in building up a European *élite*. The broadsheet indeed includes a notable suggestion for a special European staff college for training European personnel, possibly linked to the universities as a centre of post-graduate training and research.

The ways and means thus outlined, like the broad objectives they are intended to secure, do not differ greatly except in detail from the broad proposals of "Balbus", who lays first emphasis on reconstruction as insurance against chaos and bloody revolution. His careful analysis of needs and of the mistakes made after 1918 is dominated by a sense of the opportunities which are ours if we are bold and imaginative enough to seize them. The mistake of allowing private finance to dominate reconstruction work must not be repeated, and one of our first aims must be the organization of the State as an instrument of service to society. This responsibility for providing adequate security and freedom to the individual carries as corollary the obligation of a comprehensive scheme of national service from the individual.

"Balbus" sees in the schemes for relief already being mapped out by the Leith-Ross Bureau and elsewhere the stepping-stones to schemes for the development of the backward areas of Europe and Africa and the stimulation of a high level of world trade and production by raising the standard of life and the level of purchasing power in such areas. He stresses the health services and medical work, including the full utilization in Europe of all available medical personnel, notably the considerable number of refugee medical men in Great Britain and in the United States. He urges a reconstruction commission backed by international authority and armed with sufficient powers of control to ensure that neither the profit motive nor political considerations interfere with the task of re-equipping Europe. The problem must be worked out in concrete terms of needs, materials and man-hours. While he would defer the discussion of political reconstruction, he utters a warning against staking too much on economic planning and unduly neglecting political organization.

By placing all relief and reconstruction under an official reconstruction commission, priorities could be enforced which would raise the standard of life in Europe as rapidly as possible, help to develop backward areas, and impose an industrial structure which would cut across national boundaries and place grave difficulties in the way of economic autarchy. The foundation of a raw materials union should be laid in a scheme with adequate consumer representation; and by utilizing the reconstruction commission as its European agency, reconstruction could be linked with development. Moreover, the more effective these economic institutions the less paramount will become the purely political organs of power in Europe.

Such an empirical approach is in accordance with the experience of the British Commonwealth, but the acceptance by Britain of a leading position in Europe means the acceptance of responsibilities on a scale we have scarcely begun to realize. It is not merely a question of keeping an army and air force in Europe perhaps for years to come—which, as the broadsheet observes, may well entail the continuance of conscription at home and of the great Empire air-training effort in the Dominions. It is not merely a question of finding and training the extensive administrative personnel needed for the task—itself scarcely to be achieved without a drastic overhaul of the existing machinery of government and methods of selection of personnel. It is also a question of effecting a revolutionary change in our whole outlook and way of life.

First, there must be a new attitude towards Europe, both among statesmen and people. Only those statesmen can be leaders in Europe who look at things through European and not through parochial eyes, and are prepared to sacrifice what appears to be their own immediate national interests when they conflict with the true interests of Europe. Such an attitude involves a corresponding attitude among the British people and an intensive development of British education in foreign affairs to ensure that the British people regard the affairs of Europe with a more informed and realistic view.

Secondly, since the only enduring leadership is leadership by example, part of our effort for victory should consist not only in framing a vision of a world more acceptable to ourselves and to the people of Europe, but also in giving an earnest of our faith by beginning its application here and now. It is certain that Britain cannot even be the agent of Anglo-Saxondom in Europe, and promote that vital American interest in the emergence from this War of a stable and prosperous Europe, integrated into the economic life of the world, and led by statesmen who share the fundamental beliefs and values of the American peoples, unless those statesmen see in the peoples of Great Britain and the United States a dynamic and forward-looking society. To set our own house in order, and at the same time to work out for ourselves and for Europe a new and more satisfying social philosophy than either we ourselves have possessed in the past or than Europe has been offered in the existing Continental ideologies is one condition of our retaining our position in Europe. It offers not merely one of the surest prospects of continuing accord in Anglo-American relations, but also an opportunity of seizing the great opportunity that has opened in Anglo-Soviet relations.

Stimulating and suggestive as are the pamphlets referred to above, they are still more welcome for the evidence that constructive minds are already at work probing the problems and seeking to mould the mind of the nation to grasp its opportunities, and to uphold the affirmation of the Atlantic Charter that we will not once again leave unfinished the job we have taken in hand.

FORM AND CHARACTER

Why Men Behave Like Apes and Vice Versa

Or Body and Behavior. By Earnest Albert Hooton. Pp. xxv+234+22 plates. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1941.) 18*s.* 6*d.* net.

THE present eclipse of anthropology as an active science, while no doubt partly a result of the War, is very largely an outcome of the growth of nationalist doctrines in Europe during the past decade. Ever since the rise of Hitler, reputable anthropologists have been abandoning orderly scientific work in order to devote more and more of their energies to refuting *a priori* doctrines of race—for example, those which form part of the foundation of Nazi political philosophy. The immediate result has been the transformation of the international anthropological scene into one camp of propagandists which supports such doctrines, and another the main purpose of which is to expose their lack of scientific basis. A more serious consequence of the politico-racial 'red herring' is that human biology, which may be conceived as the discipline the responsibility of which is to co-ordinate studies of the biological history and relationships of different peoples, as well as studies of their genetic make-up and behaviour, has been largely side-tracked into unprofitable polemics. These fields of inquiry will have to be explored again if there is to be any sustained rational approach to the wider social problems, not least of which are the Colonial problems, which must be faced at the end of the War. That they will emerge in full vigour is certain, not only because of necessity, but also because of the enthusiastic faith shown in this field of correlated studies by a small band of devoted anthropologists and social biologists.

Prof. Hooton is one of this band in the United States. In Great Britain he is already well known for a popular exposition of human evolution entitled "Up from the Ape". Like his earlier work, "Why We Behave like Apes and Vice Versa" is wittily and vigorously written in terms understandable to the general reader, and is in scope wide enough to include both factual statements about a mass of recent findings in various fields of study and provocative opinions on a number of current topics. Its purpose is to inquire into the extent to which differences in the physical make-up of different peoples determine differences in behaviour. Perhaps it would be more correct to say that its purpose is to disclose Prof. Hooton's profound conviction that the one does influence the other, and that "environmentalists" are incorrect in attributing differences in social behaviour of different groups entirely to differences in social surroundings, habit and opportunity. For, if anything, Prof. Hooton overstates a case which few students would care to dispute. He himself would be the last to deny the view that external factors do influence behaviour, yet the polemical form of the discourse frequently makes one feel that, to prove his own point, he would go very far in disregarding them.

The book opens with an account of the functional relationships and differences in behaviour of different types of monkey and ape. This leads to the conclusion that in the sub-human categories of the order of Primates "behaviour is probably as diversified as organic structure and indissolubly associated with it"—although probably conditioned and altered by environmental adaptation. From this conclusion Prof. Hooton passes to a brief consideration of the essential differences between the human and sub-human primate, and then to a discussion of the physical and cultural diversity of prehistoric man. Again the conclusion is drawn that two types of fossil man, the Sinanthropus-Pithecanthropus group and the Neanderthal group, were almost as differentiated in behaviour as in anatomical characters.

The discussion then moves to existing man, who culturally is broadly classified according to whether his method of subsistence is "artificial" or natural, that is, food-gathering and hunting. The "artificial" group is again subdivided into "civilized" and "uncivilized" sections, which distinguish a stage of urbanization from a predominantly rural and agricultural phase of life. Prof. Hooton believes that the cultural differences between savages and countrymen on one hand, and urban dwellers on the other, are paralleled by physical differences mostly imposed by differences in motor habit arising out of their different ways of life. More detailed racial differences are also posited by Prof. Hooton, who then proceeds, by a consideration of examples from the main divisions of the human species—the Australoid, Negroid, Mongoloid and the White—to show that race may be coterminous with culture, as well as that the two are sometimes mutually independent. Their association seems well marked in such 'primitive' types as the Australian aboriginal and the South African Bushman. Their independence is, of course, usual in large mixed populations. Prof. Hooton concludes his dissertation with a vigorous statement of his belief in the existence of distinct physical types in mixed white populations and in their association with specific forms of behaviour.

It is here that the more cautious student may be inclined to find Prof. Hooton's conclusions somewhat too far in advance of the facts, and his advocacy of certain points too vigorous. The general view that physically similar individuals behave alike he has answered—as he puts it, to his own satisfaction and to the "frenzied disapproval" of others—by a study of the correlation between types of criminal offence and different physical characteristics. The original data are not discussed in the book under review, but, neglecting altogether for the moment the question of the possible correlation between crime and social and economic status, one may be permitted to make the general observation that, since conventions of 'crime' differ between different peoples and at different times, the correlation suggested by Prof. Hooton might not hold in a social environment different from the one in which he studied it.

Furthermore, while a definition of constitutional types is broadly possible, and in general referable to certain psychological distinctions—a relation which even the non-scientific man has for centuries recognized—the detailed classification of physical types which Prof. Hooton accepts presents too many anatomical shortcomings (many of which he himself points out) to justify wide generalization.

A further difficulty is that Prof. Hooton often gives the appearance of confusing the question of racial differences with that of the correlation in a mixed population of different patterns of behaviour with specific physical types. Both problems are immensely important, but they are largely distinct—even though they may overlap. Racial types cannot be created *a priori* by the anthropologist—notwithstanding Prof. Hooton's assertion that in classifying men on the basis of physical resemblance he would be prepared to put siblings, if necessary, in different racial groups.

The anthropologist's responsibility is to define the physical and psychological characteristics of declared racial groups the individuals of which are linked in blood-ties—and to do this not only in the isolated pockets of humanity where a correlation may be found between racial type and behaviour, but also in regions where a declared racial type has spread into an environment in which specific patterns of behaviour, and even specific physical characteristics, no longer remain immediately obvious. Isolation—either physical or psychological—and conversely the opposite of isolation, may be far more potent determinants of social behaviour than racial physical characters. Until the relative strength of the two factors has been decided by the most rigorously controlled observation, wide generalizations such as "human evil is not a product of human institutions but of human beings" will continue to be dangerously double-edged.

So, too, it is perhaps premature to follow Prof. Hooton in his far-reaching eugenic predictions about the possible effect of family limitation on the physical and social character of future populations. If indeed we knew enough about human biology to produce the 'better' men to whom he looks forward, why limit their number as he would have us do ? Why not fill the world with them ? The manner in which these particular views are put forward suggests, however, that some of them are Prof. Hooton's demonstrations of kite-flying, while others are Aunt Sallies, which he occasionally knocks down before the reader has a chance to get at them.

The total effect which Prof. Hooton has produced is a readable, stimulating and amusing book which demonstrates the scope of the conclusions that could be reached with fuller knowledge.

S. ZUCKERMAN.

AGRICULTURE ON A NATIONAL SCALE

Agriculture's Challenge to the Nation

By Arthur Smith. Pp. x+236. (London and Toronto : William Heinemann, Ltd., 1942.) 8*s*. 6*d*. net.

ONE of the hopeful features of our national life to-day is the widespread interest now being taken in our agriculture. Rarely have so many policies been propounded or books issued, which clearly the public is prepared to buy. There is a growing tendency to expect the State to take a larger and larger part in the business, though how far this would survive in actual practice would remain to be seen.

In the present book Mr. Smith goes further than most of his predecessors, and almost makes the farmer and the farm worker into salaried officials ; at least the risks are to be more heavily shouldered by the State and the returns both to farmers and workers are to be increased.

The author sets out to bring into use some forty-seven million acres in the United Kingdom, sixteen million being arable and thirty-one million grass. This is, of course, considerably more land than is in agricultural use at present, and the scheme necessitates a good deal of reclamation and development of rough grazings and deer forests. The main arable crops would be oats, of which there would be four million acres, half for human consumption and half for poultry and other livestock ; next would come wheat and lucerne in the dry areas ; and then enough sugar beet to provide our pre-war sugar allowance and sufficient barley to give a "reasonable drink allowance". Haymaking would be replaced by ensilage and grass drying. Beef production would be eliminated as too costly in feeding-stuffs, but as milk production is to be increased it is not at all clear what use is to be made of the bull calves inseparable from that activity. For you cannot have milk until the cow has produced a calf, and she has to go on producing a calf annually if her milk yield is to continue. Approximately half her calves are males useful only for conversion into beef. Sheep, pigs and cattle would be pastured on the hill lands, the cattle being used for butter production.

Prices would be such that the men workers would receive a minimum wage of 60*s*. a week for forty-eight hours and the women and youths would receive 48*s*. There would be processing factories in the villages at which other members of the family could work. A family might as a whole be drawing £15 weekly. The farmer would be paid according to the area of land he occupied. He would live free of rent, rates and taxes on the land he farmed. He would receive free of charge all implements and machinery, seeds, fertilizers, stock, etc., necessary to his farming, and in addition a salary of £4 per acre on the first fifty acres, £3 per acre on the next 150 acres, £2 per acre on the next 150, and £1 per acre on all acres above 350. In return, the produce would belong to the nation.

There is little doubt that farmers in Great Britain would be interested in a scheme of this sort which goes far beyond their most sanguine hopes. But the crux of the problem is this : Would the nation ? Until some big national pronouncement is forthcoming, policy-making remains uncertain.

E. J. RUSSELL.

PHYSIOLOGY OF THE AMINO ACIDS*

By DR. DONALD D. VAN SLYKE
Rockefeller Institute for Medical Research

THE number of proteins in the animal and vegetable world appears to be infinite. Yet they are all constructed of a relatively few units, namely, the amino acids. These amino acids in number are about equal to the letters of the alphabet. They have an extraordinary facility for being joined in chains; each amino acid has the same head and tail, so that the tail of one can link with the head of another, and the linking can be repeated apparently times without limit. Each amino acid has an H_2N, or amino group, which has an alkalinity about equal to that of ammonia; and each has a COOH or carboxyl group, which has an acidity about like that of citric acid. There is also a chemical group, *R*, which is different in each amino acid, and gives it its character as an individual. Hence we may call the *R* group the *individualizing* group of each amino acid. The amino and carboxyl groups neutralize each other, so that if the individualizing group is neutral the amino acid is neutral; such are alanine, glycine, leucine. However, if the individualizing group is alkaline the amino acid is alkaline; such are lysine, arginine, and histidine.

Aside from its acid or basic properties, each individualizing group bears other chemical properties. In serine, threonine, and hydroxylysine, for example, the individualizing group bears a hydroxyl with all the reacting powers of an alcoholic hydroxyl. Again, the individualizing group may carry a second carboxyl; then the amino acid is strongly acidic: such are aspartic and glutamic acids.

In cystine and methionine the individualizing group has a sulphur atom. The cystine sulphur can take up a hydrogen atom to form cysteine, and when this occurs to cystine in a protein molecule the entire character of the protein is changed. In wool and hair the sulphur is in the oxidized -C-S-S-C- form of cystine, and the proteins are utterly insoluble and indigestible. If the -C-S-S-C- is reduced to two -C-SH groups, forming cysteine, the wool is changed into proteins which are easily digested.

In proteins Emil Fischer demonstrated that the amino acids are joined, head to tail, by what he termed peptide linkings, each NH_2 group condensing with the COOH of another amino acid, with elimination of the elements of water. Simple chains of a few amino acids Fischer termed peptides. The dipeptide glycolalanine still has a free NH_2 group and a free COOH, where two more amino acids can be linked on, and the process can be repeated *ad infinitum.*

The proteins are peptides of tremendously long chains. These chains seem usually to be rolled into balls, like balls of yarn, or otherwise made to take globular or ellipsoid shape, for their rates of diffusion were found by Northrop and Kunitz to approximate to those calculated for spheres. Exceptions are the fibrous proteins, silk and wool, of which the molecules themselves appear to be extended into fibres.

In the human stomach the protein molecules meet the pepsin of the gastric juice, which unrolls the balls and breaks the overgrown chains into shorter ones, which are still fairly long, and go under the general name of 'peptones'. The chief visible change in the stomach, as noted a century ago by Beaumont in the stomach of Alexis St. Martin, is that proteins which enter the stomach as insoluble matter, such as meat or coagulated egg white, leave the stomach and enter the intestine largely changed to soluble material.

We may pause here to point out one fallacy that has crept into the practice of medicine through a perfectly correct observation by Beaumont. He noted the times necessary for various foods to remain in the stomach before they were turned into soluble material and passed on into the intestine. He found that raw egg albumin was one of the quickest protein foods to pass through. From this it has been concluded that raw egg white is one of the most easily digested proteins. The fact is that it is one of the most resistant to digestion. It passes quickly and easily through the stomach because it happens to be soluble, and it reaches the intestine largely in its original undigested state. The digestive reserves of the intestine are so great that they normally complete the work of breaking down the egg protein chains. However, the egg protein is one of those which are most likely to be absorbed in the undigested state, and to cause sensitization, particularly in infants. In fact it is said that raw egg white fed to an infant has been observed to be absorbed in such amounts that it reappeared in the urine. The most digestible form in which egg proteins can be fed is that obtained by coagulating them with thorough cooking, and then breaking the material into finely divided particles by passage through a sieve.

In the intestine the gastric products meet the enzymes secreted by the pancreas and the intestinal wall. It used to be thought that the trypsin of the pancreas had the power to break at least part of the peptide chains completely to amino acids, but it now appears that trypsin can carry the digestion no further than to the stage of peptides of the average size of six or seven amino acids per peptide molecule.

Dr. Robert Dillon and I succeeded some years ago in devising a method of analysis which was specific for free amino acids. It depended on the ability of a mild oxidizing agent called ninhydrin, which first attacked the amino group of the amino acid, breaking off NH_3 from the $R.CH(NH_2).COOH$, and leaving in its place the keto acid $R.CO.COOH$. Boiling decomposes the keto acid into aldehyde and carbon dioxide. The actual analysis consists merely in boiling the amino acid and ninhydrin together and measuring the carbon dioxide evolved.

For the series of reactions that end in the evolution of carbon dioxide it is apparent that one must have *both* an NH_2 group and a COOH group in adjacent positions, and this is the definition of an alpha-amino acid. If either the NH_2 or the COOH group is tied up in a peptide linking, the reaction cannot go through to a finish and no carbon dioxide is evolved.

With this method Dr. MacFadyen, who followed Dillon in our laboratory, was able to show that purified crystalline trypsin splits protein to peptides, but not to free amino acids, but that 'crude trypsin', comprising a mixture of the pancreatic enzymes, goes much further and splits many of the peptides into free amino acids. It is evident that the pancreas produces peptidases as well as trypsin, but that pure trypsin is not a peptidase with the power to accomplish the last step of protein hydrolysis, namely, to set the amino acids free.

Although the trypsin alone does not carry digestion to the stage of free amino acids, experiments both

---

* Substance of a paper read at the Fifteenth Anniversary Celebrations of the University of Chicago on September 23, 1941.

in vitro and *in vivo* have shown that the mixture of pancreatic and intestinal enzymes does produce free amino acids. Whether all the protein products in the intestine are digested to free amino acids before they are absorbed is not certain, but it does appear that the greater part of these products are absorbed as free amino acids. The evidence of this is that during protein digestion there is an increase in the free amino acid content of the mesenteric blood, and also of the blood of the general circulation, but reliable methods have failed to demonstrate an increase in peptide nitrogen, of which very little is present.

The speed with which digestion begins was evidenced by experiments of Cullen and McLean in which dogs were fed meat, and the blood was analysed for urea at short intervals. Within fifteen minutes the blood urea content had risen 10 per cent, indicating that a measurable part of the protein had already passed through all the stages, not only of digestion, but also of absorption and degradation. The process once started goes on steadily until absorption of the ingested protein is completed. The length of time required for completion varies in proportion to the amount ingested, but is usually 2–4 hours.

To find where the absorbed amino acids were taken from the blood, and what happened to them, Cullen and McLean anæsthetized dogs during digestion and quickly drew blood from the portal vein between intestine and liver, from the mesenteric vein leaving the liver, and from the vena cava, where blood from all the tissues is mixed. It was found that the amino acid content of the blood rose about 20 per cent as the blood perfused the intestines, and that the greater part of the absorbed amino acids were removed by the liver. In return, the liver poured into the blood of the hepatic vein an amount of urea nitrogen which almost balanced the amino acid nitrogen that had been taken up. One could watch the work of the liver in taking up the amino acids and destroying them, turning their nitrogenous parts into urea for excretion by the kidneys.

Other experiments, performed with Dr. Gustav Meyer, showed that the liver did not get quite all the absorbed amino acids, but that some escaped, and could be absorbed by other tissues. In order to magnify the effects of such absorption blood amino acid concentrations were raised to high levels by intravenous injection of amino acid solutions. Portions of muscle, kidney, and liver tissue were analysed for amino nitrogen before and after the injections. It was found that even in the fasting animal the amino acid concentration in the tissues was about eight times as great as in the blood plasma, namely, about 40 mgm. of amino acid nitrogen per 100 gm. of tissue, compared with 5 mgm. per 100 gm. of plasma. When amino acids were injected the amounts taken up by the glandular organs were much greater than by the muscles. The content of the muscles in amino acid nitrogen rose to about 60 mgm., of the kidneys to about 80 mgm., and of the liver to about 120 mgm. per 100 gm. of tissue. During the next three hours the amino acids in the muscles and kidneys remained practically unchanged, but the amino acids in the liver almost fell back to their original level, and an equivalent of urea nitrogen appeared in the circulation.

The evidence in these experiments, that the liver is the organ where urea formation takes place, supported an ancient but much contested hypothesis that the liver is the only organ that forms urea. Its unique distinction in this power was clinched by Bollman, Mann, and Magath, of the Mayo Clinic, who showed that removal of the livers from dogs led to an accumulation of amino acids in the blood, and entirely stopped the formation of urea.

The chemical steps by which the nitrogen of the amino acids is converted by the liver into urea have been demonstrated by Krebs. The nitrogen is first oxidized off as ammonia. Two molecules of ammonia then combine with one of the diamino acid, ornithine, to form the 4-nitrogen amino acid arginine. The arginine is then hydrolysed by the enzyme arginase in the liver, with formation of one molecule each of urea and ornithine. The net result is to change the highly toxic ammonia into the non-toxic and highly diffusible urea, an end-product ideally suited for transportation to the kidneys and excretion. The ornithine can go through the cycle an indefinite number of times, taking up two molecules of ammonia and giving them off as one molecule of urea. The ornithine thus acts as a true catalyst. Liver had been demonstrated years before by Dakin to be rich in the enzyme arginase, which hydrolyses arginine to urea and ornithine, but the physiological purpose of the arginase in the liver had been a mystery until Krebs' work showed its role in the final step of urea formation.

Another vicissitude of the amino acids which the work of Mann and his colleagues located in the liver is the transformation into glucose. Graham Lusk, in the early part of the century, showed that when protein is catabolized by dogs made totally diabetic by phloridzin poisoning, about 60 gm. of glucose was formed and excreted from each 100 gm. of protein catabolized. Lusk and his collaborators also showed that certain of the amino acids had their carbon partly or entirely turned into glucose when their nitrogen was turned into urea. Mann and his colleagues showed that no glucose formation from proteins or amino acids occurred when the liver was excluded.

Furthermore, the acceleration of the body's heat production that occurs during assimilation of protein digestion products was shown by Mann and his colleagues not to occur when the liver was excluded. This accelerated heat production, called by Lusk the "specific dynamic action", apparently either represents energy produced by the reactions which the amino acids undergo in the liver, or is caused by other reactions in the cells which are stimulated by the presence of products formed in the liver. Such substances must be other than the urea and glucose, for neither of these shows the observed amount of stimulating effect. The specific dynamic effect may be due either to heat evolved from reactions that occur in the liver, or to the effect of products, other than urea or glucose, in stimulating other heat-producing reactions in the body. The decision between these two possibilities awaits future exploration.

Not all the treatment met by the amino acids in the liver is destructive. During periods of heavy protein feeding the body stores considerable amounts of protein in the liver and to a less degree in the other tissues. The protein seems to be different from the structural proteins of the tissues. In the liver Berg has shown that it can, in fact, be differentiated with the microscope by its droplet structure in the cells. Functionally it is characterized by the readiness with which it is metabolized when the protein intake is decreased, or with which it is used to replace blood proteins depleted by hæmorrhage, as found by Whipple and his colleagues. It appears probable that this protein is constructed in the liver part of the amino acids brought to it from the intestine.

Besides the liver, all the living tissues of the body take their shares in the metabolism of the amino acids, for all of them are of substance chiefly protein, and it is a living protein that is continually being broken down and rebuilt from its constituent amino acids. A most interesting part of this process has recently been discovered by two Russian biochemists named Braunstein and Kritzman. It is called 'transamination', and it enables the cells to change keto acids to amino acids by replacing the oxygen atom of the ketone with ammonia, transferred to the CO group of the ketone acid from the CH(NH$_2$) of either of the dicarboxylic amino acids, aspartic and glutamic. Since at least some of the keto acids can be produced by partial oxidation of carbohydrates, transamination appears to be one of the processes by which the body can construct a portion of its own amino acids; and it has been well established that the body can in fact synthesize about half the amino acids that are found in its protein structures. The reaction of transamination is caused by an enzyme that occurs in all the tissues, but is particularly rich in the muscles.

It is a peculiar thing that only the acidic amino acids, glutamic and aspartic, with two carboxyl groups each, can give their nitrogen to keto acids. Monocarboxylic amino acids, such as glycine and alanine, cannot transfer their nitrogen to keto acids to and from each other. However, they can transfer their nitrogen to keto-succinic and keto-glutamic acids to form aspartic and glutamic acids; this is a reversible process. With aspartic or glutamic acids as an intermediary step, therefore, it seems to be possible for leucine, for example, to transfer its amino group to pyruvic acid and make alanine, or in reverse, for alanine to donate its nitrogen to make leucine from its keto acid. In either case the shifting nitrogen first is transferred to glutamic as aspartic acid, and then from that to the keto acid. The transfer is affected by an enzyme, which one of its investigators, Cohen, suitably calls transaminase; it has been separated in the form of a protein from tissue extracts and exerts its activity in the absence of living cells.

From the fact that by the transaminase action the body can build up at least some of its own amino acids it would follow that not all the amino acids in the body proteins need be provided ready-made in the food proteins, but that some can be made in the body provided the necessary products to form the keto acids are available. In fact, thirty-four years ago Magnus-Levy demonstrated that the rabbit can make the simplest amino acid, glycine. When benzoic acid is fed to an animal it is detoxified by conjugating it with glycine to form hippuric acid, which is excreted in the urine. Magnus-Levy, by feeding hippuric acid to rabbits on nitrogen-free diets, was able to make them excrete as hippuric acid more glycine than they had contained in their entire bodies. They had used other nitrogenous materials to build glycine in order to detoxify the hippuric acid. The task of finding which of the other twenty amino acids are indispensable parts of the diet and which one the animal body can build for itself has occupied some of the leading biochemists since the time of Magnus-Levy's demonstration. The names of F. Gowland Hopkins in Great Britain and of Lafayette Mendel, T. B. Osborne, and W. C. Rose in the United States have been especially brilliant in the list of those who have unravelled this problem step by step. It has required clever and painstaking work to devise diets that contained all the necessary constituents for growth except one amino acid, and to handle the animal experiments in such a manner that the results were unequivocal. In the course of these studies W. C. Rose found evidence from his rat responses that there was some previously unknown constituent of hydrolysed casein which was necessary for maintenance, and in searching for it discovered and identified the amino acid threonine. As the result of twenty years of work by all the investigators in the field, Rose finally was able to divide them all into two groups, one comprising the amino acids which must be supplied as such in the food, while the other group can be made by the body and need not be supplied in the protein food.

Essential amino acids (Must be supplied ready-made in the diet)	Non-essential amino acids (Need not be supplied in the diet)
Lysine	Glycine
Tryptophane	Alanine
Histidine	Serine
Phenylalanine	Norleucine
Leucine	Aspartic acid
Isoleucine	Glutamic acid
Threonine	Hydroxyglutamic acid
Methionine	Proline
Valine	Hydroxyproline
Arginine	Tyrosine
	Cystine

The extent to which nitrogen fed in the form of amino acids is synthesized into tissue proteins, both in the form of the fed amino acids and of other amino acids to which the nitrogen is transformed by transamination, has been studied brilliantly by Schoenheimer and his colleagues in the Departments of Chemistry and Physics at Columbia University. They have synthesized amino acids with heavy nitrogen, ^{15}N, have fed the amino acids to rats and mice, and finally have hydrolysed the proteins in their bodies and isolated various amino acids from the hydrolysates. Finally, they have analysed the isolated amino acids for ^{15}N to determine the amounts of the ingested amino acid that were built into the body proteins, both in the form of the administered amino acid and in the form of other amino acids, formed from the administered one by transamination or other reactions. They have found that incorporation begins almost immediately, and that, while more of the marked ^{15}N is found still in the amino acid with which it was administered than in any other amino acid, nevertheless a considerable proportion of the marked nitrogen was found distributed among the other amino acids.

The results of Schoenheimer and his colleagues have entirely dispelled the view that the tissue proteins when once laid down remain as unchanging structural blocks until eventually destroyed by the wear and tear of metabolism. It appears that every protein molecule in the living body is itself alive in the sense that it is continually changing and renewing its structure.

Transmethylation. The discovery of du Vigneaud that methyl groups can be transferred from methionine to other substances in the body has opened a new field rivalling in interest that of transamination. Du Vigneaud found that some substance in the vitamin B complex could be replaced by methionine. This substance he identified as choline, which is thus identified as one of the necessary vitamins. Du Vigneaud proved that the choline could be formed with the aid of methyl groups from methionine, by administering methionine in which the methyl group was marked by having one of its hydrogens in the form of deuterium. When this labelled methionine was fed to rats on a choline-free diet, choline could be isolated from their tissues with part of its methyl groups containing the deuterium. It was found that this marked methyl group could be further transferred from the choline to creatine. The methyl group of the amino acid methionine could therefore be used by the body in synthesizing two of its essential non-amino acid constituents.

Detoxifying effects of amino acids. We have already noted the manner in which the body uses glycine to combine with and detoxify benzoic acid by forming hippuric acid. In some much less obvious way cystine and methionine protect the liver from intoxication by chloroform. This peculiar effect of the two sulphur-containing amino acids was discovered in 1940 by Miller, Ross, and Whipple. They had observed that a heavy feeding of meat would protect a dog from the effects of a dose of chloroform that would have led to fatal liver degeneration if administered in the fasting state. Investigation of the different types of amino acids yielded by protein digestion proved that only the two containing sulphur had the protective effect.

Concentration of amino acids in the blood plasma and the effect of the endocrines upon it. In the normal fasting adult the concentration of amino acid nitrogen in the plasma is constant at 5 mgm. per 100 c.c. If amino acids are absorbed from a protein digest or are injected intravenously there is a transitory rise, and a return soon to the original fasting concentration. The changes in blood amino acid concentration are similar to the changes of blood sugar after administration, orally or by vein, of glucose. There is an equilibrium between the amino acids of the tissues and those of the blood plasma, with the concentration in the tissues ordinarily eight or more times greater than in the plasma. What the forces are that maintain such an unequal balance is not known, but, as in the case of blood glucose, the endocrines have been found to be factors in the control of the plasma concentration. Luck and his collaborators have shown that administration of either insulin or adrenalin lowered the plasma amino acid content of animals. Mirsky has shown that insulin greatly retarded the passage of amino acids from muscles to blood in eviscerated dogs. The effect of insulin on the blood amino acids is much like that on the blood sugar. The opposite effect, to increase the plasma amino acid content, is shown by some of the other hormones. Thus Farr and Alpert in our laboratory have recently found that intravenous administration of the growth- or metabolism-stimulating factors of anterior pituitary extract, of antuitrin, pitressin, or adrenal cortical hormone was followed in dogs by increase of the plasma amino acid content.

Blood amino acid concentrations in disease. From the manner in which hormones can influence the concentration of amino acids in the plasma it is evident that the interpretation of changes found in disease may be difficult. If the plasma amino nitrogen content were merely the mechanical resultant of inflow from the intestines balanced against absorption and metabolism by the tissues, one would anticipate that liver damage would result in a retarded removal of amino acids from the blood, in abnormally large increase in plasma amino acid content during digestion of protein foods, and in abnormally slow return of the plasma amino acids concentration to normal after injections of amino acids. In fact all these results have been reported by various authors, but they seem to be definite only when the hepatic damage has reached a severe grade. This might be expected from the experiments of Frank Mann with partially hepatectomized dogs. He found that it was necessary to remove 80 per cent of the liver before the blood amino acid content began to rise. It does not appear therefore that one can expect blood amino nitrogen determinations to afford a delicate means for detecting moderate degrees of liver injury.

In Bright's disease two extraordinary changes of plasma amino acid content in opposite directions have been observed in our laboratory. One of them was discovered by Kirk in patients in or near uræmic coma. The plasma amino acid nitrogen in some of these patients rose in a day or two from but little above the normal level to six- or eight-fold as much. If, by treatment with saline and glucose injections and other therapeutic measures, recovery from the severely uræmic state could be induced, the plasma amino acid content fell as quickly back to normal. The sudden rise might be explained as due to an accelerated tissue breakdown accompanied by a simultaneous failure of deaminizing function of the liver, but there was no independent evidence that either of these conditions occurred. The mechanism of the amino acid rise in uræmic coma remains a puzzle.

In the opposite direction, Far and MacFayden, using the ninhydrin method first worked out with Dr. Robert Dillon, showed that children with nephrosis are likely to have chronically subnormal plasma amino acid values. But, of particular interest, is the fact that when the patients have the sudden illnesses known as 'nephrotic crises', when sudden collapse occurs without infection or any other obvious cause, the plasma amino acid nitrogen shows precipitate falls to as low as 2 mgm. or even 1 mgm. per 100 c.c. Whether the cause is an endocrine-influenced shift in the equilibrium between blood and tissues, or some factor that is as yet totally unidentified, remains uncertain. However, regardless of the mechanism of the plasma amino acid fall, the injection of generous amounts of amino acids in the form of predigested milk proteins has regularly produced a marked alleviation of the collapse, and a great reduction in the mortality from these attacks.

Nutrition by intravenously injected amino acids. Shortly after early work cited in this article showed that amino acids were absorbed from the intestine during protein digestion in amounts sufficient to account for all the nitrogen digested, Henriques in Copenhagen demonstrated that nitrogen equilibrium could be maintained with intravenously injected amino acids as the sole intake. He placed a cannula in the neck vein of a goat kept in a stall, and maintained the animal in nitrogen equilibrium for several weeks by giving the great part of the necessary nitrogen in the form of a protein digest hydrolysed completely to amino acids and injected intravenously. The therapeutic application did not follow until twenty years later, when Ellman began the regular use of intravenous injections of predigested casein. He was followed by Farr and MacFadyen, who showed that the injected amino acids were assimilated fully as well as the nitrogen from ingested proteins digested in the alimentary tract. A large part of the nitrogen required can be given in this form over a period of weeks. It appears that this form of nutrition can well supplement intravenous calories in the form of glucose in conditions that prevent adequate feeding by mouth.

SIR WILLIAM BRAGG, O.M., K.B.E., F.R.S.

BRAGG'S first research paper was published in 1904, when he was forty-two years old. This fact is not without significance for an understanding of his work and character. He had gone out to Australia as a young man of twenty-four, without any experimental experience and without, indeed, any real training in physics—he was fond of telling how he learnt the elements of the subject on the boat as he travelled to take up his appointment as professor of mathematics and physics at Adelaide. He soon showed a liking for experiment and set up the first X-ray tube to operate in Adelaide, possibly the first in Australia. He made a name as a teacher and as a man of great social gifts, and might have spent a pleasant and useful life without ever carrying out any original investigations, for in those days 'research' was not a professional necessity. It was not until he had had long experience in expounding the fundamentals of his subject, and in so doing had developed a keen critical sense for what was important and what was trivial, that he set out to discover something about radioactivity, a subject that had stirred his active curiosity when he was preparing an account of what had been done in this field. So well, however, had he taught himself in those years of preparation that his first paper, on the range and ionization of alpha particles, is a classic. Within three years he had been elected a fellow of the Royal Society.

Many characteristics of Bragg's scientific work were shown in his Australian days. He never attacked a problem until he had a clear and simple picture before him of what he wanted to do, and he was never satisfied until he had a clear and simple answer to his question. The task he set himself was always one of deep significance, his exposition was always lucid and persuasive and he was always generous in his acknowledgment of the work of others. His gift of stimulating those about him to fruitful endeavour was also shown throughout his life. In Adelaide he made an enthusiastic collaborator of Kleeman, while his school of research at the Royal Institution is world-famous and has attracted students of varying degrees of maturity from all parts of the world. Nothing hasty, nothing immature, nothing of that pretentious work the triviality of which is disguised by its difficulty and obscurity ever came forth from his laboratory. His work, like his personality, was simple yet profound, sincere and compelling.

Bragg was born on July 2, 1862, the son, as he liked to recall, of a yeoman farmer of Cumberland. After a brilliant school career he went to Trinity College, Cambridge, with a major scholarship and studied in particular mathematics. He was third wrangler in 1884, gaining a first class in Part III of the Tripos in 1885. It was in 1886 that J. J. Thomson casually suggested to him that he should apply for the post at Adelaide, which he obtained, and he was professor there until 1908. He quickly endeared himself to his colleagues and fellow-citizens, showing the talent for making friends and winning affection which was so marked all his life. He never wooed popularity deliberately, being, at bottom, somewhat diffident about his own powers and qualities, but he had a charm of manner and a pretty patience with what Karl Pearson used to call "our weaker brethren" that won all with whom he came in contact. In Adelaide he married Gwendoline, daughter of Sir Charles Todd, and there all his three children were born—the present Sir Lawrence Bragg; Gwendy, now Mrs. Alban Caroe; and Robert, who was killed at the Dardanelles. Australia left a deep mark on Bragg's life and he always spoke with affection of the years which he spent there. Scientifically, this period of his life is characterized by the fundamental work on alpha rays to which reference has already been made.

In 1908 he returned to England as Cavendish professor of physics at Leeds. He speedily established his name as a teacher and wrote a monograph on alpha rays published in 1912 under the title "Studies in Radioactivity". It was in the Leeds days that he began to be deeply concerned as to the nature of X-rays, a problem which was exercising the scientific world. It had been contended in some quarters that they were of a wave nature, but the doubtful results of certain attempts to produce diffraction had militated against the general acceptance of this view. Bragg himself inclined to the opinion that they were of the nature of a particle, an electrically neutral doublet, when in 1912 von Laue's fundamental discovery revealed that they possessed the properties of light of an exceedingly short wavelength. It is characteristic of the balance of Bragg's mind that while he at once grasped the significance of von Laue's work, at the same time he still contended that a wave nature left some things unexplained. With rare prevision he wrote in NATURE at the end of 1912: "the problem then becomes, it seems to me, not to decide between two theories of X-rays, but to find, as I have said elsewhere, one theory which possesses the capacities of both."

Following a paper by his son in which the reflexion law was established he began, in collaboration with him, the classic work in which was demonstrated the existence of monochromatic X-radiation and the possibilities of applying X-rays to the investigation of crystal structure. The first joint paper, "The Reflexion of X-Rays by Crystals", appeared in 1913 and the joint book, "X-Rays and Crystal Structure", in 1915. A reprint of the early researches of the two Braggs appeared in German in 1928.

This work on X-rays and crystal structure, which Bragg often expounded in terms so simple as to make it all seem inevitable, laid the foundations of one of the most beautiful structures of modern science. It was used for fundamental advances in both inorganic and organic chemistry. Metallurgy is deeply indebted to it. The names of those who were initiated into research in this field by Bragg—if we mention Astbury, Bernal, Mrs. Lonsdale, Müller, Patterson, Monteath Robertson and Shearer we recognize that there are others with equal title to be cited—recall some of the developments for which he was directly responsible. Bragg retained his active interest in the subject and showed all his freshness of approach up to the end. His last paper dealt with the extra reflexions in X-ray photographs, which aroused all his old enthusiasm and flair for a simple explanation.

To return to his career, the War of 1914–18 found him at Leeds. He was appointed Quain professor of physics at University College, London, in 1915, but his time until the end of the War was devoted wholeheartedly to war service. He was a member of the panel of the Board of Inventions and Research from its inception, and in 1916 undertook the task of directing the acoustic work on submarine detection, which was carried through with such success. After the War he took up his professorial work at University College, but post-war conditions made the establishment of an active laboratory difficult. Good work was done, with which the names of Müller and Shearer must be associated, but in 1923, before Bragg had had time to become identified with University College, he was appointed to the directorship of the Royal Institution and of the Davy Faraday Research Laboratory.

This was in every respect a happy appointment. At the Royal Institution Bragg had full scope both for his wonderful gifts as a popular exponent of science and for his leadership in original investigation. The first Christmas Lectures which he delivered, "The World of Sound", at once made it clear that the Faraday of "The History of a Candle" had found a worthy successor. His Friday Evening Discourses gave delight to an ever-growing circle. At the same time his very broad interests—Bragg was a keen lover of music, as Mr. Mark Hambourg was reminding me recently; he was widely read; and as a young man he painted and drew with considerable skill—and his personal charm enabled him to attract to the Institution a wide variety of distinguished lecturers. His family, too, identified itself with the Institution. Until her death in 1929 Lady Bragg took a very active part in all its social life, and since then Bragg's daughter, Mrs. Alban Caroe, has played the hostess with great tact and charm; while Sir Lawrence not only delivered a set of Christmas Lectures and various discourses but has, since 1938, been professor of natural philosophy there. Bragg loved the Royal Institution and took the keenest interest in its traditions and history. He played, for example, a prominent part in the publication of Faraday's Diary.

Many honours came to Bragg from all parts of the world. In 1915, he, with his son, was awarded the Nobel Prize for physics for the work on X-rays and crystal structure. In 1931 he was admitted to the Order of Merit. From 1935 until 1940 he was president of the Royal Society, an office which he filled with conspicuous charm and unaffected dignity. He was awarded the Rumford and the Copley Medals. Through all these distinctions he retained a modest and chivalrous outlook, in which seriousness of purpose was balanced by a deep sense of humour, deep religious feeling by a complete lack of bigotry. His family life and his public life were serene, cheerful and complete. The end was sudden. His heart had troubled him for some time. On Tuesday he had to take to his bed and he died on Thursday, March 12.

E. N. da C. Andrade.

There are men of science one cannot help admiring without liking them overmuch, and there are others one likes while secretly thinking them misguided: to few is it given to be both loved and admired. Sir William Bragg was one of those few—more than that, he was said to be the best-loved man of science in the world. One just wanted to do things for him, and do them well. He was that kind of a man.

The story of the latter part of Bragg's scientific life is, of course, the story of structure analysis: he was not an active participant in everything, naturally, or the originator of every new idea, but he was the soul of everything. We who were his disciples and are his apostles had always the impulse to "tell Bragg about it" wherever we were working, for we knew that we could talk to him, that he would listen, and that he would be just as thrilled as we were. In the laboratory he would run to us just the same to tell us of any new idea that had occurred to him. He had a very human desire to share his joy, his boyish glee, and to be told that it *was* a good idea. His face would sometimes fall quite like a boy's if (very rarely!) you happened to think it was not a good idea after all—but you could always argue peaceably with him; he was your pupil just as much as you were his. That, added to his great kindliness and modesty, was, I think, the secret of Bragg's influence. There was no question of his making regular tours to discuss progress; but he might pop into your room any time to tell you something or ask you something, and it was your pride to be able to talk intelligently about the one or to answer the other.

When in 1921 I had the good fortune to become one of Bragg's assistants at University College, the first exciting days were over in which he and his son founded crystal analysis and X-ray spectroscopy, and he was turning his mind more to space-groups and organic crystals. At that time he was not really conversant with space-group theory—none of us were—for he was a physicist first and a crystallographer by implication, but he and his son had already demonstrated the laws experimentally. If I am asked to convey in a word all that the Braggs in those earlier years did for crystallography, quite apart from their stupendous contribution to spectroscopy and diffraction theory, I like to tell this story, based on the fact that nowadays straight crystal analysis runs so smoothly that it has become difficult to believe that there were once birth pangs and growing pains. There was put to me some such question as this: "Tell me, what was all this business about sodium chloride? From the theory of space-groups and a little common sense the thing could scarcely be anything else but O_h^5. You can work the whole thing out simply from atomic weights, the density and Avogadro's number. What *did* the Braggs do with sodium chloride?" To which I could not help replying, "Oh, they just proved the theory of space-groups, that's all."

Soon after the War of 1914–18, as I say, Sir William's mind became engrossed with the shapes, sizes and distribution in crystallographic space of the larger non-ionized molecules of organic chemistry, and in this field he broke first ground with that splendid investigation of the structures of naphthalene and anthracene. Not that he ever abandoned inorganic crystals or loved them any the less—witness, also about that time, what to my mind is one of the most beautiful things he ever did, the structure of ice; or his later return to quartz to explain so elegantly its modes of twinning. But he tended more and more towards organic structures, not merely as a convenient division of labour with his son's school at Manchester, where giant strides were being continued in the inorganic field, technique and diffraction problems, but also because at heart, besides being by implication a crystallographer, he was by induction a biologist, a molecular biologist. When we went to the Royal Institution in 1923 and set about helping him to re-found the Davy Faraday

Laboratory, he not long after gave a series of lectures on the "Imperfect Crystallisation of Common Things" (reported in one daily paper as the "Imperfect Civilisation of Common Things"!), and it was my privilege to provide X-ray photographs of hair, cotton, bone, sea-hedgehog spines and such-like —pretty dreadful photographs they were too, as we know now, but none the less precious, because of their associations. I would say that dating from that time Bragg saw, and saw more clearly with the passing years, that the crowning glory of structure analysis would one day be in the realms of biology. It was granted to him to live to see this dream beginning to come true in the work of his own pupils.

Those were great days when he re-made the Davy Faraday, and we all had our chosen tasks building with him—X-ray tubes and spectrometers, long-chain compounds, space-groups, basic beryllium acetate and other fascinating co-ordination compounds and organic crystals, X-ray photometry, the theory of rotation photographs, and all sorts of lovely things. Bragg himself was too busy with other duties to stick to any continuous line of research, but he lectured about all that was going on (and about much, besides, that was outside X-ray analysis), thereby revealing ever-new points of view, and from time to time he would dash back into the fray to thrash out something that had excited his eternally boyish interest. He had the most amazing faculty of taking up a subject on which he had only the foggiest ideas to begin with, and quickly improving it out of all recognition; as, for example, at the Faraday Society's discussion on "Liquid Crystals" held at the Royal Institution in 1933, when he explained the optics of smectic substances in terms of the cyclides of Dupin; and often, if you met him a few weeks afterwards, he would have reverted, not indeed to his initial fogginess, but to a state of comparative forgetfulness, just because he was pre-occupied doing the same sort of thing in some other line.

As a lecturer and writer he was pre-eminent, as everyone knows. I should say that he was the most charming and lucid scientific writer of our time. Is there anything in all scientific literature to equal the opening sentence of his "Universe of Light": "Light brings us news of the Universe"? And who among our men of science could have matched his article in *The Times* on the nation's food that he wrote at the age of seventy-eight? But one cannot even begin in this brief homage to show all the man that Bragg was. To many, like myself, he was a scientific father. Simply and affectionately we called him "The Old Man". W. T. ASTBURY.

It is seldom that the death of a leader in science brings so deep a sense of intimate and personal loss to people of all ages and conditions, as does that of Sir William Bragg. From his own contemporaries and colleagues down to the children, for whom he loved to exploit his wonderful faculty of simple presentation, everyone feels that, with this departure of another of the great ones of a great period in science, a dear and familiar friend has gone from us.

Nowhere will the loss of him be more constantly or more keenly felt than in the circles of the Royal Society. Living at the Royal Institution, a short walk from Burlington House, he was within easier access to the Royal Society and a more frequent visitor there than other presidents of recent years. It would have been impossible to miss the signs of his influence on the Society, and of his activity on its behalf during his presidential term. Bragg's period of office had seen the gathering and breaking of the storm, and he had early foreseen that Great Britain and its Government would need science as never before. He had steadily and patiently brought to bear the whole weight of his reputation and the strong influence of his personality, so impressive in its wisdom and so charming in its gentle modesty, to ensure that the voice of science should be heard, and that the Royal Society should take its place as the most widely representative of the spokesmen. The appointment of the Scientific Advisory Committee to the War Cabinet, with three officers of the Royal Society as members *ex officio*, was announced during his last year of office, and greeted by him in his last anniversary address to the Society.

The War brought him other duties also, as chairman of the Advisory Committee to the Cabinet on Food Policy, and in many other directions. Some of these duties he laid down with the presidential office, but we were eager to keep him in consultation and still to have the benefit of his wisdom and experience, wherever possible. I hope that we did not keep him at work too long; for, though he had found it necessary to limit his physical effort, he remained so alert, so quick in understanding and so clear in his memory, that it was difficult to think of old age in connexion with him. For two months from Christmas, when I had to go away on other duty, he came back to the presidential chair; and so he remained, quietly at work and ready to give a helping hand anywhere, right up to the few days of illness which brought the end—the close of a long life of whole-hearted devotion to science and to the interests of his fellow-men. H. H. DALE.

By the death of Sir William Bragg, British science loses its most distinguished physicist, while a much wider section of the nation loses also a friendly guide who interpreted the results of science to them with great lucidity and charm. Sir William Bragg's work in furthering the application of science in both Government and industry may not, however, be so widely known and appreciated.

Throughout his life, and particularly in his later years, he saw ever more clearly how the practical applications of scientific work were becoming first the luxuries and then the necessities of human life, and realized that, in consequence, only by organized and appropriately directed scientific research could any industry serving the community continue to thrive. He always advocated, too, the need for the greater incorporation of the results of science in national affairs, but warned us that "it is science itself, not scientists, that we are trying to lift to the high places. . . . We do not claim that scientists shall be entrusted with authority because they are scientists: we do claim that authority shall be exercised in the light of a knowledge which grows continuously and with continual effect on politics, on industry, and on thought itself."

Sagely he added: "If we, in the continually increasing contacts of scientists with current affairs, can show that we have something of great value to contribute and that we give it freely, placing our individual interests below those of a greater purpose; if we try to understand the motives and principles of those whom we meet who may not share our vision, just as we may fail to appreciate theirs, then by so doing we have the best chance of bringing about the changes that we desire."

The contacts of this kind which he personally established were wide and numerous. During the War of 1914–18 he acted as a scientific adviser to the Admiralty, devoting his attention to the problem of submarine detection. During the present War he has been frequently consulted on a variety of scientific matters and has been chairman, since its formation, of the Committee advising the War Cabinet Food Policy Committee on scientific aspects of war-time food problems. He has also been a member since its formation of the Scientific Advisory Committee established under the chairmanship of Lord Hankey. As he himself pointed out, the significant feature of these committees was their close and direct association with the Cabinet, so that scientific advice was brought into Government at the highest possible level.

It was the same appreciation of the place of science in everyday life and in industry that led him to accept appointment to the Advisory Council of the Department of Scientific and Industrial Research, of which he was still a member at the time of his death. But he counted his duties as a member of this body insufficiently discharged in the formal business of meetings, and the young men of science in both the Department's own stations and in the laboratories of the research associations will long remember his heartening and inspiring visits, when the distance between senior and junior magically vanished and both hopes and difficulties were shared.

Edward Appleton.

Every journal devoted to scientific learning has been deprived of an unfailing source of light and leading by the death of Sir William Bragg; but none can have benefited more than Nature from his wisdom and judgment. It is with a full and grateful heart that I remember many occasions when he readily gave guidance upon subjects in which his special knowledge as well as his wide interests were of particular value, and when his contributions to its pages enlightened the readers of this journal. With a diffidence which was natural to him, he often suggested, when asked for copies of addresses or lectures delivered by him, that he doubted whether Nature would find much in them suitable for publication, though his printed words were always as highly appreciated as his spoken utterances and the light of them penetrated to a much greater distance than the sound.

Sir William Bragg's first communication to Nature was in 1908, and its subject was the nature of γ- and X-rays. He was then at the University of Adelaide and had entered the new and wonderful field of physics opened by the discovery of radioactivity and the isolation of the electron. In the following year he became Cavendish professor of physics in the University of Leeds, and a year or two later I induced him to prepare a monograph bringing together, under the title of "Studies in Radioactivity", methods and results of investigations of the phenomena attending the passage of the new types of radiation through matter. This monograph was the first of his published books. As editor of the series to which the volume belonged, I was able to make a few suggestions upon its scope and structure, but with the characteristic generosity shown to all associated with him in work of any kind, Sir William referred to me at the end of the preface in the words: "He has been most kind in allowing me to benefit by his experience. He set me my task, but he has done his best to make it an easy one."

Our friendship began with the production of this volume thirty years ago, and throughout this period I have followed with fraternal affection the leading part played by Sir William in the renaissance of modern physical science through the development of his pioneer studies. It would be presumptuous for me to praise the insight and the ingenuity which he used to reveal regularities of arrangements of atoms and molecules by the method of X-ray analysis; but with all his friends I share personal pride in his great achievements, and thankfulness that his son, Sir Lawrence Bragg, remains with us to continue to explore this fertile field.

By their individual and joint researches, what began as an academic study soon extended into the fields of applied science and has now become a subject of prime importance in the understanding of many industrial processes. They have enabled us to see and trace patterns in the structure of matter previously beyond the sight of man though not beyond his imagination. In one of his sonnets, Michael Angelo beautifully expressed the similar function of a sculptor to unfold a form hidden in a block of marble, in the words:

> The very sculptor can no thought conceive,
> That does not lie deep buried in the stone.
> And this, the eye discovereth alone,
> That doth commandment from the mind receive.

Just as light becomes visible only when it impinges upon matter, so natural knowledge has to be perceived before it can produce enlightenment. Sir William Bragg was not only a rich source of such knowledge, but also the creator of waves of thought with which every intelligent mind could make appreciative contact. His style of exposition was effective because it was simple and unpedantic in scientific substance or literary embroidery; and his messages appealed, therefore, to all classes of the community. He was an acknowledged master of scientific craftsmanship in a field of work to which he devoted the greater part of his life, and also a creator of designs and a convincing exponent of their beauty. With the desire for truth always in his heart, and the pursuit of it in the domain of verifiable knowledge as the purpose of scientific inquiry, he combined wise counsel and the might of understanding, and has bequeathed to the world a splendid heritage to be treasured with affectionate memory.

R. A. Gregory.

The loss of Sir William Bragg will be felt by physicists all over the world. His rare combination of experimental skill with lucidity of thought and pre-eminent clarity of exposition would have marked him as an outstanding figure in any generation. But he will be remembered among his many friends almost more for his kindliness and charm, especially to the younger generation. He was always ready, as I know from my own experience, to discuss any problem, even with a young undergraduate, on equal terms. Argument and contradiction never ruffled him. Even when he appeared to be caught out by some contradiction, such as were only too easy to construct in the days when we were all fumbling for the explanation of the quantum paradoxes, his serene imperturbability was never disturbed. All the scientific honours heaped upon him made not the slightest difference to his modest and unassuming manner and address. He was a man who can never have had an enemy and who has left an abiding mark in the memory of his innumerable friends.

CHERWELL.

THE late Sir William Bragg's wide influence upon contemporary science is universally acknowledged. It was always his desire that men of science should throw aside the cloak of mysticism and seclusion and appear as other men striving after truth in no matter what field of action. This view has recently acquired especial significance because of the great service to the State which science, when properly applied, is now generally seen to be capable of giving; and it was this attitude of mind that largely prompted his delight in simplifying, so far as possible, for the benefit of others many of the highly complex problems of physics with which his name is so closely connected. Thus his lectures were remarkable for their clarity and experimental illustration. The underlying motive was always to let others see and understand what his own clear vision could discover.

The Royal Institution afforded ideal facilities for research and exposition, which exactly suited Bragg's temperament. He showed in many ways how deeply he felt the honour and responsibility of following in the footsteps of Faraday. Sir William's versatility was particularly noticeable in the courses of Christmas Lectures to Children, which he delivered in 1919–20 upon "Sound", since it was then that his interest in music suggested many ingenious illustrations. For the series he gave in 1931–32 he chose "Light" as the subject and dealt fully with the nature of colour and colour mixtures. In this connexion it may be pointed out that during the last meeting of the British Association at Cambridge, an exhibition of pictures by members was arranged, and there Sir William showed several charming water-colour landscapes which he had painted when abroad. His Christmas Lectures were memorable occasions for many reasons, because the presence of children always stimulated in him those fascinating qualities of friendliness and enthusiasm which were a dominating characteristic of his nature. His quick mind often enabled him to make a witty reply to a question, but it never wounded.

After each of the Christmas lectures there were delightful tea parties in Sir William's private rooms.

We, at the Royal Institution, deplore the loss of one whose guidance in all affairs was so invaluable and fair-minded. We cherish the memory of his invariable courtesy, kindliness, enthusiasm and loyalty to the great traditions of his calling. He was beloved by all.

CHARLES E. S. PHILLIPS.
(Hon. Sec. Royal Institution.)

IN the death of Sir William Bragg we lose a great man and well-tried friend; and, distinguished as have been his services to science and to the State, it is the sense of personal loss, the tribute to his rich human qualities, which now dominates. The loss was so completely unexpected; age had not withered him; his wide and generous knowledge was ready to hand and at the service of all real inquirers; his interests were as fresh as ever, and his unique power of lucid exposition seemed to grow greater as time passed this tract on electromagnetism, which saw the light but a month or two since, is a model of its kind).

His pioneer contributions to physical science have provided a probe for the scrutiny of the submicroscopic world and, equally with these investigations, his faculty for seizing on essentials, for reducing a complex problem to its simplest elements, for describing physical phenomena with incomparable clarity and charm, made him a most fitting head of an institution the traditions of which are so intimately associated with the names of Davy and of Faraday.

A little incident comes to mind which may serve to illustrate these qualities. A paper was read before one of our societies by a young investigator who, with the blundering particularity of youth, insisted on describing methods and results with such indiscriminating zeal and detail, that his audience was left completely befogged. Perfunctory applause had died down, when Sir William rose, and in a five-minute speech gave a masterly sketch of the paper, which showed it for the sound piece of work that it was, cleared the mists from the minds of his hearers, and left the author heartened and encouraged.

Friendliness and helpfulness were of the essence of his being; and though institutions may remain, while those who direct their activities come and go, it is difficult to think of the Royal Institution without Sir William's friendly presence, guiding and leading the researches of the laboratory and informing the work of the Institution with the spirit of Faraday.

May his memory long be kept green!

ALLAN FERGUSON.

THOUGH it was a great pleasure to meet Sir William Bragg anywhere and on any occasion, it is on his own ground at the Royal Institution that most of us best remember him. The setting so became him; and he so graced the setting. Whether receiving the guests on a Friday evening, or expounding some of the mysteries of science in the great lecture theatre, or merely entertaining some stray scientific visitor to tea, Bragg had the art, which was no art because it was rooted in real interest and a genuine affection for humanity, of making the visitor feel at home. Any scientific society which might have been fortunate enough to obtain the privilege of holding a meeting in the Institution would usually find on arrival that the Director, by some happy chance, had business which took him into the entrance hall, and the visitors would receive from him friendly informal greetings which made them feel that they were not intruders, but welcome guests. In the work and welfare of the younger generation of men of science Bragg's interest was almost paternal.

In his early work Bragg made some fundamental contributions to the science of radioactivity. He was, I believe, the first to point out that gamma rays and X-rays behaved, in many respects, like uncharged particles: an idea with which modern quantum theory has now familiarized us. His remarkable work on the elucidation of crystalline structures by X-rays, carried out in collaboration with his son W. L. (now Sir Lawrence) Bragg, has founded a new branch of science, and has forged a new and valuable weapon in the armoury of industrial research. X-ray analysis is now being applied to the study and improvement of an amazing variety of commercial products.

As an interpreter of physics to the public Bragg was unrivalled in the present age. His discourses at the

Royal Institution, illustrated with all the resources at its command, were a sheer delight. Simple yet profound, the non-scientific hearer could gather a clear mental picture of the subject discussed, while the professional man of science enjoying the apparently effortless artistry of the presentation usually found that, in addition, he had gained some quite new side-lights on a subject with which he had thought himself completely familiar.

J. A. Crowther.

Nearly twenty years ago, as a young graduate, I joined the team of research workers at University College, London, who were inspired and led by Sir William Bragg. His was a charming personality and he was an ideal research professor. Keen on his own work, bubbling over with enthusiasm at each new discovery; just as interested in ours, yet never obtrusive, never impatient. We knew that he shared our joy at each idea proved correct, because he himself had such an astonishing intuition. He knew where to look for knowledge; but although intuition showed him the way, he was never satisfied with less than the most complete proof that the knowledge attained was fundamentally sound. An admitted mistake found him sympathetically understanding; like Faraday, he never regarded time as wasted if it increased experience. Yet he could be stern on occasion: a young man who spoke slightingly of one whose lifetime had been spent in determining one physical constant really accurately was most surprised to receive a sharp rebuke. Such painstaking and unspectacular labour Sir William knew to be the very cornerstone of research.

Sir William attracted and welcomed to the laboratories of the Royal Institution workers from all parts of the world, and most of them must remember with gratitude not only the opportunities for scientific research and discussion thus afforded but also, and perhaps not least, the delightful garden parties given at his country cottage at Chiddingfold. Those of us who are still working on the problems that enthralled him to the last, feel that we have lost not only a leader but also a personal friend.

Kathleen Lonsdale.

NEW FELLOWS OF THE ROYAL SOCIETY

The following were elected to the fellowship of the Royal Society on March 19:

Prof. J. H. Burn, professor of pharmacology, Oxford, formerly dean of the College of the Pharmaceutical Society; distinguished for his work in physiology and pharmacology and on the principles and methods of biological standardization.

Dr. F. M. Burnet, assistant director of the Walter and Eliza Hall Institute for Medical Research, Melbourne; distinguished for his researches in bacteriology, especially on avian and mammalian viruses.

Dr. M. Dixon, lecturer in biochemistry, Cambridge; distinguished for his work on tissue respiration and respiratory catalysis.

Prof. E. C. Dodds, M.V.O., professor of biochemistry, Middlesex Hospital Medical School; distinguished for his investigations in biochemistry in relation to physiology and medicine and especially in the synthetic production of œstrogenic agents.

Mr. A. Fage, principal scientific officer, Aerodynamics Department, National Physical Laboratory; distinguished for his contributions to the experimental study of aero- and hydro-dynamics, particularly in relation to turbulent flow.

Colonel N. H. Fairley, A.A.M.C., consulting physician in tropical diseases, director of special research, Hospital for Tropical Diseases, London; distinguished for his researches in tropical medicine.

Mr. P. Hall, university lecturer in mathematics, Cambridge; distinguished for his contributions to pure mathematics, particularly in the theory of groups.

Prof. G. H. Henderson, professor of mathematical physics, Dalhousie University, Halifax, Nova Scotia; distinguished for his work in radioactivity and particularly in the investigation of pleochroic haloes.

Prof. T. P. Hilditch, professor of industrial chemistry, Liverpool; distinguished for his work on the chemistry of natural fats.

Prof. E. Hindle, regius professor of zoology, Glasgow; distinguished for his work in parasitology, and on the cytology of artificial parthenogenesis.

Dr. C. S. Hanes, senior scientific officer, Low Temperature Research Station, Cambridge; distinguished for his researches in botany and biochemistry, especially the first enzymatic synthesis of starch.

Prof. A. Holmes, professor of geology, Durham; distinguished for his work in petrology and the applications of radioactivity to geological problems.

Prof. D. M. Newitt, assistant professor of chemical technology, Imperial College, London; distinguished for his work on high-pressure technology and for his researches on combustion.

Dr. C. C. Paterson, O.B.E., director of the Research Laboratories, General Electric Company, Wembley; distinguished for his work in promoting physical and industrial research.

Dr. J. K. Roberts, assistant director of research, Colloid Science Laboratory, Cambridge; distinguished for his investigations by physical methods on adsorption and other surface phenomena of importance in catalysis.

Dr. H. W. B. Skinner, Wills research fellow and lecturer in spectroscopy, Bristol; distinguished for his work on the X-ray spectroscopy of the solid state, leading to results of importance in the theory of the structure of metals.

Prof. D. Thoday, professor of botany, Bangor; distinguished for his researches in plant physiology, particularly those dealing with photosynthesis, causal anatomy and the water relations of plants.

Prof. A. R. Todd, professor of chemistry, University of Manchester; distinguished for his researches in organic chemistry, notably the synthesis of vitamin B_1 and other natural compounds of physiological importance.

Prof. A. E. Trueman, professor of geology, Glasgow; distinguished for his work in palæontology, particularly on molluscan faunas of the coal measures.

Mr. A. H. Wilson, university lecturer in mathematics, Cambridge; distinguished for his contributions to the electronic theory of solids and for his work on the properties of metals.

NEWS and VIEWS

Tributes to Sir William Bragg

Elsewhere in this issue, a few of the innumerable friends of Sir William Bragg, and representatives of bodies concerned with the various phases of his activities, pay their tribute to him. In particular we would endorse Sir Richard Gregory's reference to Sir William's services to Nature; and we may add that his wisdom and advice, given in characteristically kindly and modest manner, remained at our disposal right up to the end. His abiding interest in crystal analysis was reflected in a communication published in Nature of December 27, 1941, p. 780, on the problem of the diffuse spots in X-ray photographs.

At the memorial service in Westminster Abbey held on March 19, a great company of those who had been associated with Sir William during the course of a long life of service in the cause of science showed by their presence the honour in which he was held. H.M. the King was represented by Earl Fortescue, the president of the Board of Education attended, and scientific societies and Government Departments were represented by their officers. The Archbishop of Canterbury and the Dean of Westminister took part in the impressive service: the Lesson was taken from I Corinthians, xiii, concluding with the words, "the greatest of these is charity"—surely an apposite phrase to associate with Sir William Bragg's memory. Prof. E. N. da C. Andrade has ably summed up Sir William's many-sided character in verses he wrote as a dedication to his book "Engines"; we quote these lines:

You, by a twofold excellence
Raised to deservèd eminence,
Not only Nature can compel
Her enigmatic oracle
To breathe to you, but can convey 't
Clear to the uninitiate.

. . . .

Three times yourself at Christmastide
Have charmed us as the children's guide,
In ice and snow's fantastic frond
And close-compacted diamond
Have shown the wonders that abound,
And wandered through the World of Sound:
And have most curiously displayed
How science guides the hand of trade.

Dr. J. de Graaff Hunter, C.I.E., F.R.S.

News has been received from Sir Gerald Lenox-Conygham of Dr. J. de Graaff Hunter, formerly director of the Geodetic Branch, Survey of India, who is a prisoner in Germany. Dr. Hunter had gone to California to represent Great Britain at the Pacific Science Congress which was to be held there in September 1939, and it had been his intention to spend the winter there; his wife and daughter were with him and it was thought that the climate of California would be good for his daughter's health. When war was declared, he found himself unable to obtain money from England and was obliged to move to some place in the 'sterling' area. He thought of Jamaica, but eventually decided on Nassau in the Bahamas. He had in the meantime written to the Surveyor-General of India offering to return to India to serve in his old department in any capacity; and after some considerable time, he learned that he would be welcomed back in India. Dr. Hunter then went from Nassau to New York, intending to take ship to Cape Town and after arrival in Cape Town to plan the remainder of the journey. He accordingly sailed from New York in the steamer *Zam Zam* on March 15, 1941. This ship was attacked and sunk by a German raider when she was about three days from Cape Town. The passengers were put on board a supply ship and were at sea in her for a long time. Eventually they were landed at a port near Bordeaux and were conveyed by slow stages to internment camps in Germany. Dr. Hunter's address is: Gefangennummer 102872, British Civilian Internee, Ilag VIII, Deutschland; Mrs. Hunter and her daughter are at Interniertenlager, Liebenau, Würtemburg. Letters are being received both from Dr. Hunter and from Mrs. Hunter, from which it appears that they are tolerably well.

Breeding of Mosquitoes in Static Water Supplies

The Limmer and Trinidad Lake Asphalt Co. Ltd., has issued a memorandum of notes on mosquitoes breeding in static water supplies. It is written by J. F. Marshall, director, British Mosquito Control Institute, in collaboration with K. W. Attwooll, chief chemist to the above-named company. From among the thirty different species of mosquitoes known to inhabit Great Britain, only *Culex pipiens* is at all likely to breed in ordinary water-storage tanks. It is, furthermore, a species that rarely or never bites man. Two other species, namely, *Theobaldia annulata* and *Culex molestus*, occur in such tanks under special conditions only. The first-named breeds almost exclusively in water fouled through contamination with sewage or other nitrogenous matter. *C. molestus*, on the other hand, appears to select water located in dark underground places such as basement-stored water. It is pointed out that static water supplies in open-air tanks need never be changed or treated from October until March inclusive since *Culex pipiens* is then in hibernation. At other times treatment need only be applied when necessary to allay public apprehension of the presence of breeding mosquitoes. In so far as the other two species are concerned, any larvicide used should be non-injurious where asphalt or bituminous rendering has been employed for water-proofing purposes. This means that oiling of the water is undesirable; also it is deleterious to the rubber of stirrup pumps, etc. Disinfectant fluids of the nature of coal tar derivatives are harmless in the above connexions and at the same time effective larvicides at about one part in 28,000–50,000, according to circumstances. Their use is therefore preferable and to be recommended.

Entomology of Commerce

At the annual general meeting of the Society of Public Analysts and Other Analytical Chemists held on March 6, a lecture on "The Entomology of Commerce" was delivered by Prof. J. W. Munro, director of the Biological Field Station, Imperial College of Science and Technology, Slough. After a brief description of the main types of insects responsible for damage to foodstuffs and other materials, Prof. Munro mentioned some instances in which the ravages of certain insect pests have been traced to economic causes; for example, troubles from wood-boring insects due to importation of long-stored timber, and appearance of new types of infection in tobacco due to certain importations from Africa. Combating insect pests by cleanliness and rigorous control of storage conditions may suffice with materials initially sound, but is inadequate with materials imported in a highly infected condition. Work on this subject is being carried out at the Biological Field Station at Slough. Destruction by heat has been employed against wood-boring insects. Low temperatures are used in the tobacco trade; the resistance depends on the rate of cooling, and improved results have been obtained by a second cooling after an intermediate warming. Studies of the insecticidal action of some inert powders have given promising results; the action appears to be due to withdrawal of moisture. In discussing chemical insecticides that act in vapour form, Prof. Munro directed attention to the influence of various factors, such as temperature, and inequalities of distribution, and gave some results obtained in studying them. Investigations are in progress to elucidate the mechanism of insecticidal action and so to ascertain what properties are necessary in an insecticide to enable it to penetrate the epicuticle and cell-walls of an insect and upset the normal processes within.

National Astrophysical Observatory of Mexico

A NUMBER of distinguished scientific men from both North and South America took part in the Inter-American Scientific Conference held in Mexico during February 15–26, on the occasion of the dedication of the new National Astrophysical Observatory of Mexico. President Manuel Avila Camacho, of Mexico, in issuing invitations to the conference, said: "The purpose of the Mexican Government is to contribute to the maintenance, in the American continent, of the progress of science and culture, and thus counteract as much as possible, the paralysation of scientific and cultural activities in the countries devastated by war". The new Observatory is situated on land provided by the Government of the State of Puebla, near a small town of Aztec origin called Tonanzintla, about 80 miles east of Mexico City. Under the direction of Prof. L. E. Erro, observations of the southern Milky Way will be made with a 24–30-in. Schmidt camera, the most powerful telescope in the tropics. This instrument will be similar to the Jewett telescope at Harvard Observatory, and its mounting is at present under construction in the Harvard shops. Its location in lat. 19° is of great importance for studies of the southern skies, which are inaccessible to instruments farther north. The climate is excellent for observation, especially during the winter. The programme of the Observatory includes variable-star studies, and observations of meteors and the sun.

Carnegie Trust for the Universities of Scotland

THE fortieth annual report of the Carnegie Trust for the Universities of Scotland covers the academic year 1940–41, and includes details of the interim distribution of grants, the endowment of post-graduate study and research, assistance to students and an abstract of financial accounts for the year ended September 30, 1941 (Edinburgh: Carnegie Trust for the Universities of Scotland). Of the three who were elected to fellowships at the beginning of the year, two are still working in universities, and of the nine awarded senior scholarships, five (of whom four were women) completed the session's work. Of the forty-five scholars elected at the beginning of 1940–41, nineteen resigned immediately upon appointment or requested that their scholarships be suspended on account of war service. Of the thirty-five fellows, senior scholars and scholars elected in July 1941, thirteen have similarly asked that their awards be held in suspense, while three others were unable to accept owing to war work.

Reference is made in the course of the report to Dr. Webster's and Mrs. Hickie's work on the synthesis of compounds of possible value as anti-malarials, and to R. R. Coats's investigation on the interconversion of aromatic sulphonic acids and sulphones and on syntheses of sesquiterpene derivatives. J. Forrest has synthesized certain complex hydrocarbons and thrown much light on the reactions of fluorene, while A. B. Grant's work on the chitin of crab-shell has advanced our knowledge of chitose. Mention is also made of the work of Dr. W. Tebrich and Dr. J. M. Robson on the degree of penetration of sulphonamide compounds into the ocular tissues of rabbits when they are superficially deposited on the eye (see NATURE, Dec. 6, 1941, p. 695) and of Dr. J. D. Loudon's work on the mutual effect of substituent groups in benzene derivatives. The decrease in the assistance to students, amounting to 171 beneficiaries, was mainly among male students in the faculties of arts, law and divinity.

Biological Research in China

THE latest issue of *Sinensia* (2, No. 5–6, September, 1940) that has come to hand will be found an encouraging record of good work from the National Institute of Zoology and Botany, Academia Sinica, Peipah, Szechuan (China). With one exception the twelve contributions that go to make up the issue are the work of Chinese investigators. From the zoological point of view the most important papers are by Sicien H. Chen on leaf-beetles (Family Chrysomelidæ). This author proposes to raise the six sub-families that form this group to the status of separate families. This change implies that each of these families would become of the same taxonomic significance as the well-established families Cerambycidæ and Bruchidæ in the superfamily Phytophaga. In a second contribution the same author contributes extensive "Notes on Chinese Eumolpidæ", which deal with their classification and include descriptions of a number of new species. From the botanical side S. H. Ou's "Phycomycetes of China" (II) is a notable and well-illustrated paper. S.C. Teng's "Studies on Chinese Timber Trees in reference to Forest Management" (I) is a timely investigation now that the forests of China have come to a stage when they require systematic management.

Universities' Federation for Animal Welfare

THE fifteenth annual report of the Universities' Federation for Animal Welfare (UFAW) reports continued activities in its educational and research work; but as few students of the University of London are now in London college activities have been temporarily discontinued. More than six thousand copies of the Federation's new natural history lecturettes have been contributed at cost price to local education authorities. Much work is being done on the humane side of mole- and rabbit-trapping, and authenticated information is being collected from biologists. UFAW is not in entire agreement with the Ministry of Agriculture's war-time rabbit-trapping arrangements in allowing steel traps to be set in the open, and prefers the rabbit to be exterminated as a pest and not preserved for the trapping industry. It disagrees with recent attempts in rural circles to re-stock warrens that have been exterminated in the war-time rabbit campaign. The Federation has recently issued a leaflet directing attention to the condition of the Canadian beaver, noting that more than fifty thousand beavers a year have recently been trapped in Canada. It plans to promote Parliamentary bills to prohibit the sale of rabbits mutilated by gin trap or snare, and to prohibit the sale and manufacture of gin traps. Its Bill to prohibit the setting of gin traps in the open and making rabbit extermination compulsory became law in 1939.

Lice

UNDER the title "Lice" the British Museum (Natural History) has added another pamphlet to its Economic Series (1942). The author, Dr. John Smart, gives a very clearly written account of these creatures affecting man, including their life-history and how infection takes place. A short statement regarding louse-borne diseases is also included and there is a useful section dealing with the prevention and treatment of lousiness. The pamphlet is well up to date and includes some of the most recently acquired information. In its thirty-two pages are comprised all the essential facts likely to be required by non-technical readers. It can be obtained from the Museum or through a bookseller, price 6*d*.

Geophysical Institute of the Andes

THE Geophysical Institute of the Andes, just inaugurated in Bogota, Colombia, at the new Colegio de San Bartolome, is the most important one in South America, the only one in Colombia, and one of eight under the Southern Cross. It is directed by two Jesuits, the Rev. Simon Sarasola and Jose Ramirez, the latter a graduate in seismology at St. Louis. The seismological station is about 8,745 ft. above sea-level, and half-way up the Andes del Norte.

The Hebrew University, Jerusalem

Two hundred and ninety-five students have graduated at the Hebrew University, Jerusalem, during the last eleven years. 90 per cent of them have found employment of a nature permitting them to continue their studies in Palestine. Thirteen graduates found occupations abroad, mostly in the United States, and fifty-six continue with scientific and research work in the University itself, in the Hadassah Hospital, the Palestine Government, or other public institutions.

Hermann C. Vogel, 1842-1907.

HERMANN CARL VOGEL, the German astronomer, was born at Leipzig on April 3, 1842. He was the youngest son of Dr. Vogel, a well-known schoolmaster and a brother of Edouard Vogel (1829–56), the African explorer. From the University of Leipzig young Vogel entered Leipzig Observatory and assisted Zöllner in researches on solar prominences. From 1870 until 1874 he was in charge of von Bülow's observatory at Bothkamp in Holstein, where he did spectroscopic work on the sun, the planets, stars and nebulæ. When the German Government in 1874 founded the Astrophysical Observatory at Potsdam, Vogel became one of the assistants, with Spörer and Lohse as colleagues. With Müller he prepared a spectroscopic star catalogue containing particulars of 4,051 stars, and in 1887 with Schreiner began the measurement of the radial motion of stars. He took an active part in the work of the International Chart of the Heavens and in many ways furthered astronomical science. His honours included the Valz Prize of the Paris Academy of Sciences, the Gold Medal of the Royal Astronomical Society, the Draper Medal of the U.S. National Academy of Sciences and the Prussian Order of Merit. He died at Potsdam on August 14, 1907, leaving by his will 17,000 marks to the Berlin Academy of Sciences for the encouragement of research in astrophysics. He had been director of the Potsdam Observatory since 1882, and at his death he was succeeded by Schwarzschild.

Night Sky in April

THE moon is full on April 1d. 12h. 32m. U.T. and new on April 15d. 14h. 32m. Lunar conjunctions with the planets occur as follows: Venus on April 11d. 16h., Venus 0·1° N.; Saturn on April 18d. 05h., Saturn 3° N.; Jupiter on April 20d. 01h., Jupiter 5° N.; Mars on April 20d. 17h., Mars 6° N. On April 4d. 04h. Mars will be in conjunction with Jupiter, Mars 1·7° N., and on April 28d. 09h. Saturn will be in conjunction with Uranus, Saturn 1·6° S. Mars, Jupiter and Saturn are still well placed for observation in the evening. Venus is a morning star and rises about 4h. in the middle of the month. On April 27d. 20h. 15·3m. the star β Virginis, mag. 3·8, will be occulted by the moon. An interesting binary, γ Virginis, has components of nearly equal magnitude, 3·6 and 3·7 respectively; the separation is 5·75″. The Lyrid meteor shower will be active during April 18–22; the radiant is at R.A. 18h., N. Dec. 33°.

Announcements

THE second lecture on the Science and Citizenship Foundation will be given by Prof. Lancelot Hogben at the annual general meeting of the Science Masters' Association, at 8 p.m. on April 9, in the Temple Speech Room, Rugby School, Rugby. The subject will be "Biological Instruction and Training for Citizenship". The lecture is open to the public without fee; tickets may be obtained from Mr. W. Ashhurst, Grammar School, Stretford, Lancs, or from Mr. H. J. Harris, 5, Barby Road, Rugby.

THE Town and Country Planning Association has organized a Conference on Industry and Rural Life which is being held at Newnham College, Cambridge, during March 27–30. Separate sessions will be devoted to agricultural planning and policy, decentralized industry, social life in villages, architecture, rural land-ownership, and design of new towns. Among those taking part are Sir Daniel Hall, Sir Montague Barlow, Prof. Patrick Abercrombie, Mr. L. F. Easterbrook and Prof. Sargent Florence.

ERRATUM.—In the article "The Sun and the Ionosphere" (NATURE, March 7, p. 277), line 9 from foot of Column 1, the word "ultra-violet" should have appeared before "radiation".

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

A New Method in X-Ray Crystallography

The classical methods of X-ray crystallography give either the spacings but not the positions of the reflecting planes (if monochromatic radiation is used, as in the rotating crystal and powder methods), or the positions but not the spacings (if white radiation is used, as in the Laue method). X-ray 'goniometers' (Weissenberg, Schiebold-Sauter) give both positions and spacings, but only for one layer line at a time. In what follows a method will be described which gives directly both spacings and positions of the reflecting planes for all diffraction spots in a rotation or oscillation photograph on flat film.

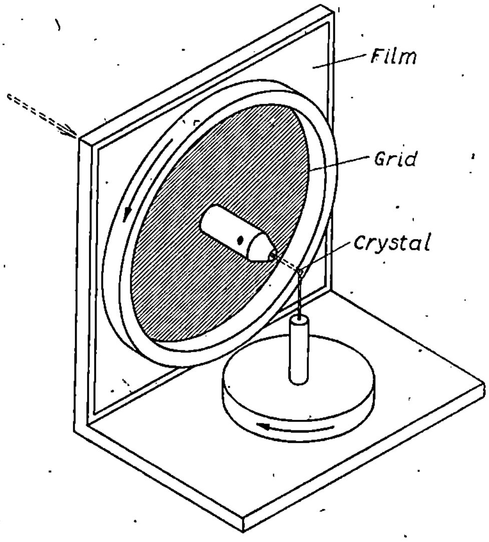

Fig. 1.

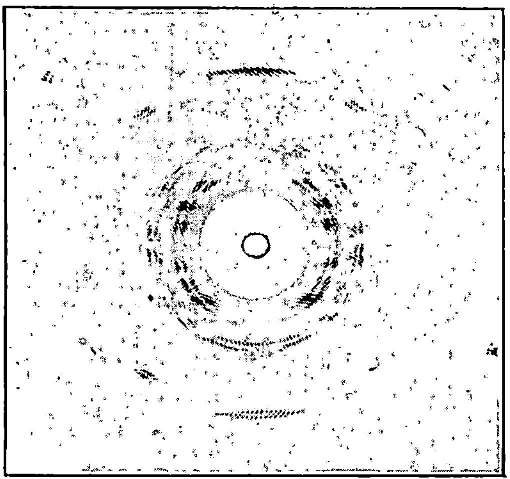

Fig. 2.
CENTRAL PART OF BACK-REFLEXION ROTATION PHOTOGRAPH; NaCl CRYSTAL, COPPER $K\alpha_1 + K\alpha_2$ RADIATION. NATURAL SIZE; DISTANCE CRYSTAL–FILM 28·5 MM.; PINHOLE 1/8 MM.

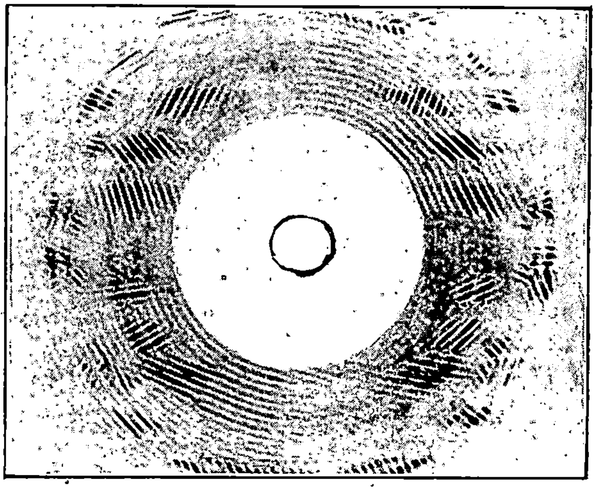

Fig. 3.
CENTRE OF FIG. 2 ENLARGED BY 2·4 DIAMETERS.

The apparatus differs from the usual rotating crystal arrangement only by the addition of a fine grid of thin parallel wires, placed close in front of the film, and rotated in its own plane during the exposure (Fig. 1). The rotation of the grid is mechanically linked with that of the crystal; provided that the total rotation of the grid does not exceed 180°, one position of the grid will correspond to one position of the crystal. The shadows of several wires appear as fine lines upon every diffraction spot (Figs. 2 and 3); they reveal the position of the grid wires and so the position of the crystal at the moment of reflexion. Thus the position of the reflecting planes in the crystal is given by the inclination of the shadow lines, while their spacing is obtained from the position of the diffraction spots by means of Bragg's law.

The photograph shown in Figs. 2 and 3 was taken with a back-reflexion arrangement, shown schematically in Fig. 1; in this case the tube of the pinhole can be used as the axle around which the grid rotates. Crystal and grid were rotated by a synchronous motor with slipless wire drive. The grid was made of copper wires (0·19 mm. thick, 23 wires per cm.) stuck to a strong 'Cellophane' sheet by 'Durofix'. Technical details will be given elsewhere. Fig. 3 is a part of Fig. 2, enlarged by 2·4 diameters; it does not show fully the sharpness of the shadow lines because the enlargement has been much over-exposed in order to make the structure of the background visible (see below). The angles between the shadow lines and a reference line are easily determined by a microscope with turn-table, mechanical stage, and cross-wires in the eyepiece. In the photograph Fig. 2 they could be read off with an accuracy of about ± 0·1°. The method offers a simple and quick way of determining crystal orientations; a detailed communication will appear elsewhere.

Originally, the method was developed for the investigation of internal strains, lattice curvatures, submicroscopic inclusions, and other irregularities which cause the diffraction spots to be drawn out to streaks. In such cases usually neither the classical nor the goniometer methods can reveal without ambiguity the character and orientation of the reflecting elements. The rotating grid method shows directly the positions of the crystal at which the different points of the streak were reflected, and thus provides information about irregularities similar to that provided by the classical methods about regular structures.

Fig. 3 shows that the shadow lines are not confined to the Bragg reflexion spots but often can be followed far into the background. (These straight lines in the background must not be confused with the concentric circles which are a trivial consequence of the rotation of the grid about the central spot.) Consequently, a large proportion of the background in the surroundings of a spot had been reflected simultaneously with the spot. This opens up the possibility of analysing the origin of the background in terms of contributions from individual atomic planes. Part at least of the structure of the background would seem to be due to the 'diffuse' ('dynamic') reflexion of X-rays, caused by the thermal vibration of atomic planes. In a system of shadow lines extending from a Bragg reflexion spot into the background, the dark stripes are produced by the total radiation coming from the crystal, while in the light stripes the radiation contributed by the lattice plane of the Bragg reflexion is screened off. Thus the difference of the intensities represented by the dark and the light stripes at two neighbouring points is the intensity diffracted by the lattice plane of the adjacent Bragg reflexion. This provides a means of quantitative measurements of the diffuse reflexion from individual lattice planes. The photograph Fig. 3, taken at room temperature, shows that the method can be used even at low temperatures, if, by a suitable choice of the radiation, the glancing angle of the lattice plane is brought sufficiently near to 90°.

Another possible use of the new method is for obtaining information about the mosaic imperfections of crystals. If the speed of rotation of the grid, but not that of the crystal, is increased, the contours of the shadow lines must become blurred as the transverse movement of the wires during the time of reflexion begins to be noticeable. If the primary beam is collimated by a perfect-crystal monochromator, this effect should give a direct measure for the X-ray imperfection of the crystal.

I am indebted to Sir Lawrence Bragg and to Dr. H. Lipson for valuable suggestions.

Nitrogenous Character of Penicillin

PENICILLIN purified as described by Abraham and Chain[1] contains nitrogen. The interpretation of low positive results in the Dumas analysis of less pure material was made uncertain by the failure to respond to the usual qualitative test and by low results in Kjeldahl estimations. However, traces of pyridine have been recognized, by the characteristic absorption spectrum, as a product of the action of boiling concentrated sulphuric acid on the purest material. With this material the Kjeldahl method, under vigorous conditions, gave the same result as the Dumas. The barium salt, dried at 100° *in vacuo* over phosphoric anhydride (no further loss at 120°), contains (Weiler and Strauss): C, 44·3; H, 4·85; N, 4·13 (Dumas), 4·2 (independent micro-Kjeldahl); C-Me, 11·6; Ba, 22·0 per cent (independent estimation 21·3). There was no phosphorus or sulphur, and no O-Me or N-Me groups. These results are in fair agreement with the formula $C_{24}H_{32}O_{10}N_2Ba$. This is provisional, and C_{23} and C_{25} formulæ are not excluded. The barium salt is strongly lævorotatory in aqueous solution. The absorption spectrum does not suggest that aromatic rings are present in the molecule. Hydrolysis affords one carbon dioxide molecule and other products, including a water-soluble volatile acid, and a substance giving a sparingly soluble picrolonate, flavianate and aurichloride.

While it is possible that the above observations hold for pure penicillin, we cannot definitely claim homogeneity of the material in the absence of the usual criteria of purity.

Bactericidal Effects of *Aspergillus clavatus*

IN preparing enzyme concentrates from certain moulds, antibacterial activity was noted in material from a number of species characterized by high proteolytic capacity. Thus two strains of *Aspergillus clavatus* were found to be capable of sterilizing liquid media which had been infected with *Staphylococcus aureus* and other organisms. These moulds invest simple liquid media such as Csapek Dox solution with distinct antibacterial properties. Small portions of the medium on which the mould has been grown inhibit the growth of *Staphylococcus aureus* in glucose broth and other media. Larger quantities of medium are bactericidal, no viable organisms being demonstrable after the mixture of broth and medium has been incubated for several hours. In intermediate dilutions an initial phase of bacteriostasis may be followed by bactericidal action. The active substance differs from penicillin not only by being bactericidal as well as bacteriostatic, but also in several other respects. First it is relatively stable; filtrates may be handled without sterile precautions, and even high acidity is well tolerated. Aqueous solutions may be boiled without being inactivated. Furthermore, the substance inhibits the growth of, and in higher concentrates kills, a number of organisms that are not attacked by penicillin.

Concentrates of the active substance are obtained by absorbing it on charcoal directly from the liquid medium after removal of the mycelium, and by afterwards eluting the dried charcoal with ether. The ether-soluble fraction shows bactericidal potency in dilutions of 10^{-5}. Occasionally more potent fractions were obtained.

Antibacterial activity is also demonstrable in presence of serum, pus and urine. The medium and active concentrates thereof were administered without adverse effect to mice, to healthy human subjects and to a number of clinical cases. The protective effect *in vivo* remains to be studied in greater detail, but it appears that the active fraction inhibits strains of organisms which proved resistant to such agents as sulphonamides or mandelic acid.

My thanks are due to Prof. H. Raistrick, Mr. George Smith and Dr. Harry Coke for much help and advice.

Potable Water from Sea-Water

I WAS surprised that in his article on "Potable Water from Sea-Water" Dr. A. Parker[1] makes no reference to what seems to a biologist an obvious method—that found in the Bowman's capsule of the kidney. If a pressure greater than the osmotic pressure is applied to a solution bounded by a semi-permeable membrane, pure solvent will go through the membrane. The osmotic pressure of sea-water is about 450 lb./sq. in., a pressure reached over an area of 1 sq. in. by quite small car jacks with no more effort than can be applied with one finger. The only difficulty should be the semi-permeable membrane, and I suggest that research might profitably be devoted to producing a suitable one. It would not need to be perfect; if it let through 15 per cent of the salts, a two-stage pump would produce a liquid within the limit suggested by Dr. Parker for potability.

W. B. YAPP.

Manchester Grammar School.

[1] NATURE, **149**, 184 (1942).

IT was not possible in my relatively short article to mention all the methods, which have been suggested, for obtaining drinking water from sea-water. The intention was only to indicate the main principles of the methods.

Suggestions of the kind mentioned by Mr. Yapp have been considered. If a method involving the use of a semi-permeable membrane as a filter under pressure is to be suitable for use under conditions similar to those in open boats, it must meet the following requirements: It must be simple to operate. The membrane must be so robust or so supported that there is little or no risk of the membrane being broken or perforated during transport and use. The rate of passage of the drinking water through the membrane must be reasonably high, say about one pint an hour. It is also desirable in the particular circumstances that the treated water should not contain more than about 100 parts of salt in 100,000 parts; this means the removal of at least 97 per cent of the salt in sea-water.

Ultra-fine membranes of the collodion type under pressures of the order of 250 lb. per square inch have been used in experiments for the Water Pollution Research Board for the removal of bacteria from liquids and for the separation of finely dispersed colloids from saline solution. Experience has shown that although the rate of filtration is very slow, salts such as sodium chloride readily pass through these membranes. It may be that intensive investigation would lead to the discovery of a membrane satisfying the requirements, but the problem presents so many difficulties that the prospects of solving it within a short time are not great.

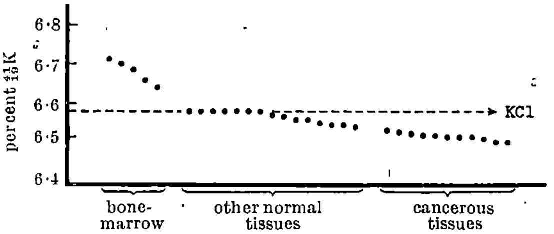
An Isotopic Shift of Potassium in Human Bone-marrow and Cancer

IN previous investigations it has been found that the isotopic constitution of potassium contained in bone-marrow and tumour tissue from the rat was appreciably different from that of potassium in various other normal rat tissues, the shift observed with 'bone-marrow potassium' being opposite to that observed with 'tumour potassium'. As regards potassium in normal tissues other than bone-marrow, the content of the heavy isotope, $^{41}_{19}$K, usually proved to be very close to that of mineral potassium as contained in ordinary potassium chloride (A.R.); only in a few exceptional cases was the $^{41}_{19}$K content slightly decreased[1,3]. However, with potassium in bone-marrow (that is, bone including marrow), a marked and regular increase in the content of $^{41}_{19}$K was obtained; on an average, the increase was 1·9 per cent[1,3]. This result agreed with earlier findings on potassium in bone-marrow from horse and beef[4]. A similar shift was further obtained with potassium present in rat blood plasma[2,3]. On the other hand, potassium in Jensen rat sarcoma showed a distinct decrease of its $^{41}_{19}$K content, and a similar result was found with potassium in mouse sarcoma 37*S*. The average decrease for both tumours was 1·1 per cent[1,5].

It was of interest to carry out similar investigations on potassium contained in human tissues. This has been done, so far, with postmortem material, taken as a rule twenty-four hours after death. A number of normal tissues ('non-cancerous' tissues in a stricter sense) were tested; they included five samples of bone-marrow, taken from lumbar vertebræ, and fifteen samples from liver, kidney, lung, spleen, brain, heart and skeletal muscle. All the samples were derived from organs which showed, on macroscopical examination, little or no pathological changes. Further tests were made with various kinds of cancerous tissue, consisting of eight samples of primary carcinomas which originated from liver, kidney, lung, stomach, colon and rectum, and of three samples of secondary carcinomas (metastases) of the liver. The preparation of ashes and the technique of mass-spectrographic analysis were similar to those previously described[3,6].



CONTENT OF $^{41}_{19}$K IN POTASSIUM PRESENT IN CERTAIN TISSUES FROM HUMANS.

Dotted line indicates content of $^{41}_{19}$K in mineral potassium as contained in potassium chloride, A.R.

The results are illustrated in the accompanying figure. Each recorded point indicates the percentage of $^{41}_{19}$K in potassium contained in one ash sample; the whole of the values is arranged in a descending order of magnitude, independently of the tissues concerned. It will be seen that there are five values which are above the level represented by the $^{41}_{19}$K content of mineral potassium; the increase is, on an average, 1·5 per cent. These values were obtained with bone-marrow. Another group of fifteen values corresponds to the other normal tissues mentioned, seven values being identical with the $^{41}_{19}$K content of mineral potassium and two fairly close to it. The six remaining values are slightly below this level. A more marked decrease, however, was obtained with cancerous tissues: all the eleven values were lower than any of those found with normal tissues. (The two highest values correspond to samples from secondary liver carcinoma.) On an average, the content of $^{41}_{19}$K was by about 1·0 per cent smaller than that of mineral potassium.

It can be said that the results are in general agreement to those obtained with corresponding tissues of animal origin. As in that case, the $^{41}_{19}$K content of potassium in bone-marrow is higher than that of mineral potassium and potassium in other normal tissues, while potassium in cancerous tissues shows regularly a lower content of $^{41}_{19}$K than that of potassium in every tested normal tissue. In particular, there appears to be some lack of agreement, especially if one considers that six of the values found with normal tissues have shown a certain approach to those obtained with cancerous tissues. In accounting for these values one has to remember that potassium in normal rat tissues showed occasionally a similar deviation, and it is further necessary to consider the possible influence of post-mortem changes and of pathological conditions in the tissue other than cancer formation. It is of interest to note, in this connexion, that three of the six tissue samples concerned originated from cancer cases, while the nine other tissue samples belonging to this group were obtained from non-cancer cases only. This might indicate that potassium in non-cancerous tissues of cancer-bearers approaches in its isotopic constitution that in the cancerous tissue: a conclusion which is consistent with previous findings on potassium in muscle tissue from tumour-bearing rats and mice[5].

Sheep Strike by the Fly, *Phormia terrae-novae* R.-D., in North-east Scotland

DURING May–July, 1941, my colleague, Mr. W. Moore, who is studying pesticides in the North of Scotland College of Agriculture, Aberdeen, accidentally found the fly, *Phormia terræ-novæ* R.-D., attacking sheep in north-east Scotland. In the last week of May, when fly-strike had become fairly general, Mr. Moore decided to clean out and disinfect the breeding-chamber for flies and to restock it with a fresh supply of the sheep maggot fly, *Lucilia sericata* Meigen, bred from maggots found on sheep. The first eleven batches of maggots were obtained from sheep on widely scattered farms. Each batch of maggots was reared under fly-proof conditions. The flies that emerged from the eleven batches of maggots were *Phormia terræ-novæ* R.-D. The species seemed the cause of primary strike in many cases. This is the first record of it striking sheep in north-east Scotland. Not until the second week of July did Mr. Moore obtain maggots of *Lucilia sericata* from sheep, and then he found it mixed with *P. terræ-novæ* in two cases. Later strike by *L. sericata* seemed to become general.

Since strike was very common during 1941 in the north-east of Scotland and since the species responsible for it was not investigated in most cases, it seems probable that *P. terræ-novæ* occurred commonly in strike, at least early in the year. Macleod[1], Haddow and Thomson[2], and Macleod[3] have recorded this fly striking sheep on the mainland of Argyll and in Mull, and in some instances the strike was apparently primary.

Very little is known about the habits and life-history of the insect in Great Britain; for example, the food of the majority of its larvæ is unknown. The insect is abundant in north-east Scotland. Some adults apparently hibernate, for I caught a female in April 1929, a male on March 30, 1930, and a female on April 9, 1930, in the loft of a house in Aberdeen. The flies seem to reach their maximum numbers towards the end of July and to disappear from the open during September–October. Between July 18 and October 10, 1933, I caught in a single trap in my garden in the suburbs of Aberdeen 799 females and 559 males (compared with 863 females, 96 males *Lucilia sericata*), and between June 13 and July 27, 1934, in five traps on a farm of the Rowett Research Institute, Aberdeen, 1,915 females, 1,078 males (compared with 2,249 females, 265 males *L. sericata*).

The traps were baited with carrion, which is highly attractive to the flies, though they rarely breed upon it according to my observations of insects bred from carrion. The only time I bred the insects on carrion—and this is somewhat doubtful, for the flies may have struck the sheep when it was still alive—was at Dornie, Ross-shire, where I found a number of puparia among the wool of a sheep that had died some weeks previously. The puparia were found on May 22, 1940, and flies emerged from them during June 2–10, 1940. Smirnov[4] found *P. terræ-novæ* the chief species of fly visiting baits of meat exposed in the open air in the U.S.S.R.; it seldom oviposited on them; its larvæ occurred chiefly in kitchen refuse.

Evans[5] found it the most resistant of four species of blowflies to high temperature and various humidities. In my trapping experiments I found the fly the most resistant of about thirty species of flies to the effects of chloroform.

RESEARCH ITEMS

Floral Morphology and Angiosperm Phylogeny

THE *Transactions and Proceedings of the Botanical Society of Edinburgh* (33, Pt. 2; 1941) contains the presidential address by J. R. Matthews upon floral morphology and its bearing upon the classification of Angiosperms. His review makes it abundantly clear how every concept associated with the classical view that floral organs are necessarily modified leaves has been challenged at one time or another. The recognition of stamen and carpel as sporophyll forms, which led to the attempt of Arber and Parkin to reconstruct a hypothetical pro-angiospermic type allied to the Bennettitales, called forth Chamberlain's emphatic statement that any such origin of the Angiosperm must be regarded not merely as improbable but as impossible. Hooker is quoted from a letter to Newell Arber, dated 1907, as holding to Robert Brown's view of the Angiosperm orders "being reticulately, not lineally, related" and there is an interesting discussion of the phylogenetic value of the polyadelphous character of the stamen. Thus the typical stamen may be regarded as the result of a progressive shortening of a dichotomizing branch system while Hunt (1937), as a result particularly of a study of stigma and style, has similarly concluded that the carpel may be traced ultimately to a dichotomous branch system. There is no discussion of Grégoire's rejection of homologies between reproductive and foliar organs, but McLean Thompson's decision that the inferior ovary is 'acarpous' is presented. Grounds are given for the conclusion that "there is clear evidence also of a re-awakening of interest in the problems of taxonomy and phylogeny".

Chemistry of Pterins

AT a meeting of the Royal Society on March 19 Sir Frederick Gowland Hopkins described some experiments chiefly concerned with a derivative from pterins. These pigments have become prominent of recent years, partly on account of the prolonged efforts (1925–1941) of Continental workers to determine their nature. The progress of these constitutional studies has quite recently become dramatic. Moreover, one pterin at least has been shown to occur in mammalian tissues, with probable physiological functions there. The derivative examined involves an oxidation by molecular oxygen in solution of low pH. On the acid side of neutrality its formation proceeds throughout a wide range of pH values, but not at all on the alkaline side. From one pterin (erythropterin) the yield is large. From another (xanthopterin) it arises only in special circumstances, which are of considerable interest. The properties and behaviour of this derivative (which in some respects are exceptional) are described. No evidence bearing on the actual constitution of the product has yet been obtained. It seems justifiable to claim, however, that until the structure of this derivative is determined and the mechanism of its formation made clear, the chemistry of the pterins will remain incomplete. Another section of this paper deals briefly with the yellow products which occur when aqueous suspensions of uric acid are heated in sealed tubes at high temperature. These show properties strikingly akin to those of the pterins, and in particular yield purple derivatives in precisely those circumstances which lead to the formation from the natural pigments of the products dealt with in this paper which they closely resemble.

Submarine Contours of the North Pacific

SONIC sounding has increased our knowledge of the details of bathmetrical relief. F. Betz and H. Hess have produced in the *Geographical Review* of January a map of submarine contours of the North Pacific ocean based on the United States Hydrographic Office chart of that ocean in 1939. The detail now available allows the authors to discuss anew the probable structure of the ocean floor. The most interesting suggestions relate to the large number of trend lines in the relief. An orientation N. 75°–80° is particularly notable, but others cross these trend lines, and in particular the Hawaiian rise or swell, the main axis of which is N. 55°–75° W. The shape and other characters of the Hawaiian swell suggest that it is not, as often supposed, a folded ridge, but a fissure or perhaps tension crack accompanied by the extrusion of large amounts of volcanic material. Probably the extrusion covered a long period of geological time. The down bending of the crust beneath the load would account for the slight longitudinal depressions along the margins of the swell. The authors further suggest that the fissure, as, indeed, other Pacific fissures, opened along the strike, so that the origin of these structures is in transcurrent folds which would also explain the relative straightness of these trend lines. Other transcurrent faults in continental structure are cited, and their configurations shown to agree with the Hawaiian and Pacific rises generally. All are not associated with volcanic outpourings.

Magnetostriction in Permalloy

Messrs. Williams, Bozorth and Christensen, of the Bell Telephone Laboratories staff, have found (*Bell Lab. Rec.*, 20, No. 2, Oct., 1941) that magnetostriction in 68 per cent nickel permalloy varies by a factor of ten when the metal is subjected to heat treatment while being oriented in different directions in a magnetic field. Magnetization was also found to affect the elasticity and rate of damping of mechanical vibrations of this material. The tests were conducted on a hollow rectangular specimen wound with long thin coils to form a closed magnetic circuit, thus avoiding demagnetizing effects. The minute changes in dimensions, corresponding to a few millionths of a centimetre for each centimetre length of the specimen, were measured by reflecting light from a small mirror, which was rotated slightly by the expansion or contraction of the material caused by magnetostriction.

Torque on a Silicon Iron Crystal in a Magnetic Field

A DISK cut from a single magnetic crystal generally tends to rotate into a preferred position when placed in a magnetic field. This tendency usually increases with field strength up to saturation, but for some directions of magnetization it has recently been found to pass through a maximum, decreasing with further increase of field strength. R. M. Bozorth and H. J. Williams (*Bell Lab. Rec.*, 20, No. 2, Oct., 1941) have recently shown that this behaviour can be explained by the domain theory of magnetism, which describes a magnetic material as consisting of groups of atoms acting as units. When placed in a magnetic field, these units tend to turn into the direction of the field, the specimen tending to rotate as a whole. Calculations show that for some directions of magnetization, this tendency passes through a maximum as the domains change their alinement under an increasing field. The calculations are confirmed by the authors' experiments, in which the tendency of the crystal to rotate is determined by supporting it on a wire between the poles of an electromagnet and measuring the twist of the wire necessary to counteract the torque.

Impulse Electric Strength of High-voltage Cables

AN official communication (Ref. L/T126) from the British Electrical and Allied Industries Research Association is presented by R. Davis, of the National Physical Laboratory, in the February issue of the *Journal of the Institution of Electrical Engineers* (89, Pt. II, No. 7), giving the results of tests made mostly on virgin paper-insulated single-conductor cables of the solid or mass-impregnated type, but in addition on varnished-cambric, non-bleeding paper, H-type multicore, and belted-type cables. The conclusions reached refer only to the cables tested. The minimum impulse electric strength of virgin mass-impregnated paper-insulated single-conductor and multicore screened cable is approximately constant at 1,000 kv./cm., being independent of the voltage rating and of the sectional shape of the conductor, whether circular or elliptical. The effect of the wave shape of the applied surge on the puncture voltage and of repeated applications of surge voltage less than that necessary to cause puncture, is small. In general the positive puncture value is a few per cent higher than the negative. With impulse-voltage stressing, the non-bleeding and varnished-cambric types of cable punctured at a lower voltage than the fully impregnated types. While no direct comparison has been made between aged and unaged cables which are otherwise identical, the tests have failed to differentiate between the behaviour of aged and virgin cable with impulse voltages. The research continues.

The Electric Spark

AN important contribution to the study of the electric spark is contained in a paper read recently by J. M. Meek before the Institution of Electrical Engineers in which the author first discusses the inadequacy of the classical theory of spark discharge when applied to long gaps at atmospheric pressure. A brief description of the streamer theory of the spark follows, which latter not only explains the observed sparking phenomena but also incorporates a criterion, based on atom-physical considerations, facilitating the calculation of the breakdown potentials of different gaps in which the field distribution is known. For gaps in which corona is observed to precede sparkover, the corona onset voltage is that determined. The results of such calculations for various types of gaps are described, with particular reference to the sphere-sphere gap. Various features of point-plane breakdown are also mentioned, and an explanation is given for the occurrence of the upward-growing positive streamer from the earthed plane when the high-voltage point is of negative polarity. It is further shown that in the case of lightning discharge from a negative cloud to earth in open country, upward-growing positive streamers from the earth are not likely to be more than a few metres long and thus will rarely be observed. Irradiation and statistical time-lag are dealt with in some detail. Various experiments are described, and it is shown that quite different results can be obtained according to whether the gap is illuminated or not by the light from neighbouring spark-gaps. The effect of such irradiation is found to be important for short gaps and for gaps several cm. long, and in particular for the positive impulse breakdown of a sphere-gap when the spacing is greater than that corresponding to the Toepler discontinuity. The lowering of spark-over voltage for uniform and non-uniform gaps by the intense light radiated from a nearby spark source was also investigated and an explanation of the various results obtained is given in terms of the new theory of the spark.

Concrete at Low Temperatures

THE problem of concreting in freezing weather frequently arises. It is well known that the structural value of concrete if 'frozen' may be utterly destroyed, and consequently present-day methods prescribe that if concrete is placed in freezing weather it will be heated and maintained by insulating material at temperatures well above freezing point. The additional use of calcium chloride has been suggested, as it speeds the attainment of strength and reduces the time during which protection is necessary. As a small quantity of calcium chloride reduces the freezing point of water by only a few degrees, it has been assumed that calcium chloride would not prevent the freezing and destruction of concrete cooled well below freezing point. J. C. Yates, of the Calcium Chloride Association, working at the U.S. National Bureau of Standards, has made specimens of concrete at 70° F. containing 0, 2, 3 and 4 per cent of calcium chloride by weight of cement, immediately placing them in rooms kept at various temperatures maintained between 20° F. and 40° F. (*J. Frank. Inst.*, Jan., 1942). The specimens were removed one day before testing, and it was found that with the exception of the plain concrete all had gained strength. At 28 days, the plain concrete at 25° F. had a strength of 1,130 lb./in.^{2}, at 32° F. a strength of 3,150 lb./in.^{2} and at 40° F. a strength of 3,790 lb./in^2. The addition of calcium chloride increased the strength at all temperatures and ages. The earlier the age and lower the temperature the greater the effect. With 4 per cent calcium chloride, the 28-day strength at 20° F. was 1,370 lb./in.^{2}; at 25° F. the strength increased from 1,130 to 3,030 lb./in.^{2}.

Galactic Absorption and Apparent Distribution of Spectral Types

GEORGE ALTER has shown that the absorption conditions in a uniform and continuous absorbing galactic layer can be determined by the observed relation between colour index and absolute magnitude, and limits are given for the absorption coefficients (*Mon. Not. Roy. Astro. Soc.*, 101, 2, 84). The influence of this absorbing layer was shown to be dependent on a parameter *b*, the qualities of which are discussed in a recent paper on the subject (*Mon. Not. Roy. Astro. Soc.*, 101, 8). The investigation is extended to absorbing layers which are either discontinuous or non-uniform, or both, and thus includes irregular absorbing clouds. Various conditions of interfering absorbing matter are assumed, and an attempt is made to derive the relation between true star distances and those determined by observed colour indexes. Alter shows that this interfering matter is responsible for falsifying the average mixture of spectral types, and in some cases the mixture falsification under certain assumptions becomes very complicated. Deductions of the investigation are confirmed by an instance from a colour index examination in a region of absorbing clouds.

COFFEE GROUNDS IN ANIMAL RATIONS

By W. KING WILSON
Harper Adams Agricultural College

DURING war-time the urgent need for more foodstuffs for human consumption results in oats and other feeding stuffs commonly used for animals being largely diverted from animal rations, for which therefore other materials must be found. Among the substitutes for concentrates in the rations of the domestic group of animals (for example, pigs, poultry and rabbits), household food scraps have to make a large replacement. For this purpose house-waste is collected individually, or in some urban areas by the local authority. The majority of the food-scraps are of approximately known feeding-stuff value, but the values of some ingredients that may be present, such as coffee grounds, are more problematical. Coffee grounds are not generally used as a feeding stuff, but during the War of 1914–18 coffee grounds were collected and fed to livestock in many parts of Germany[1], although the digestibility of their crude protein was very low, namely, 11–20 per cent.

The general chemical character of spent coffee grounds is illustrated by two samples of dried coffee dregs from the second infusion which gave the following composition[2], per cent: water, 9·45 and 11·42; fat, 11·64, 12·45; nitrogen, 11·68, 11·5; caffeine, traces; starch, 17·00, 22·47; sugar, traces; ash, 1·71, 2·03; nitrogen-free extras, 14·81; and fibre, 25·30 (second samples).

Coffee dregs have been fed to cattle (beef and dairy), horses, pigs, rabbits and poultry (chickens and ducks). They were found to be more suitable when powdered and fed very dry, instead of as grains. The following amounts could be consumed daily: steers 3·3 lb., cows 2·2, horses 1·7, but preferably only up to 0·8 lb.[2] From other experiments it transpired that not all animals would eat the finely ground coffee dregs[3]. When horses received 1·1 lb. daily, in place of a similar quantity of oats, it produced nervous excitement. Apart from these scanty reports there is little guidance as to the feeding value, if any, of coffee dregs as an animal foodstuff in war-time rations.

Although Great Britain is primarily a tea-drinking country, during 1935–37 the apparent annual consumption of coffee rose from 294 thousand hundredweights to 302 thousand hundredweights and may have increased further since the introduction of tea rationing. The weight of refuse grounds available must be very considerable, and the frequency with which they will be mixed with the general household food waste makes it desirable that further information as to their value should be obtained. (To cope with the high production of coffee, Brazil destroyed 30 per cent of the pre-war crop. In the period June 1931–August 1938 more than 74,000,000 hundredweight were thus destroyed. Stocks remained high and coffee planting was forbidden. United Kingdom imports were then almost entirely confined to high-grade coffee from East Africa, India and Costa Rica.)

In 1939 observations were made in the Rabbit Section of the National Institute of Poultry Husbandry on feeding small quantities of coffee dregs in the maintenance rations of different types of rabbits. For the first two or three days this material was generally left uneaten, but by reducing the concentrates most of the animals were soon induced to eat the fresh coffee dregs, up to the equivalent of 10 per cent of the concentrates, although a few individual animals remained adamant in their refusal. Afterwards the following small experiment was initiated to continue through the period of winter food scarcity, prior to the growth of appreciable quantities of spring greenfoods.

Twenty adult rabbits were divided into two equal groups, of similar live weight, housed in individual hutches and fed on mixed rations consisting of approximately 8·3 oz. roots, 1·7 oz. hay, and 2·3 oz. mash to the control group, while the other group had 10 per cent (on dry matter basis) of the concentrates replaced by fresh spent coffee grounds. Four times the weight of fresh moist grounds were fed to replace one of dry food. The daily quantities were modified slightly to a level where the coffee group cleared their daily ration, and roots were fed more extensively. The roots and hay were fed in equal quantities to both control and coffee-fed groups. The details of food consumption are set out in Table 1, by periods of lunar months.

TABLE 1.—AVERAGE DAILY FOOD CONSUMPTION (OUNCES).

	Control			Coffee			
Period	Mash dry	Roots, etc	Hay	Mash, dry	Coffee	Roots, etc.	Hay
1	2·32	8·29	1·71	2·09	0·93	8·29	1·71
2	2·14	11·20	1·77	1·93	0·86	11·20	1·77
3	2·05	11·20	1·71	1·85	0·82	11·20	1·71
4	2·05	11·20	1·71	1·85	0·82	11·20	1·71
Average	2·14	10·48	1·73	1·93	0·86	10·48	1·73

There was a noticeable tendency for the coffee grounds to be left until the other foods had been eaten, thus indicating that they were less palatable, although better than nothing, and were consumed in moderation up to 0·8–0·9 oz. On both of these rations the general condition and live weight were maintained, although there was a slight temporary drop, but this was due to seasonal modifications in the feeding of roots during frosty weather, and affected both groups. Apart from this their condition was maintained and later showed the usual small gains in live weight, in both the control and the coffee-fed animals, as seen in Table 2.

TABLE 2.—AVERAGE LIVE WEIGHTS.

	Control	Coffee	Difference
	lb. oz.	lb. oz.	oz.
Initial L. Wt.	8 6·50	8 6·30	−0·20
1 Month	8 2·90	8 4·60	+1·70
2 ,,	8 1·20	8 1·20	—
3 ,,	8 8·70	8 4·50	−4·20
4 ,,	8 11·20	8 9·40	∓1·80
Average Gain	4·70	3·10	−1·60

Apart from improvement in live weight and body condition, there were regular observations of the fur development. There was a slight tendency to lose the coat gloss in the first period on coffee, which was followed by heavy shedding of the fur of four of the coffee-fed animals. Otherwise the general condition of the fur of both groups was generally good during the feeding of both rations. The only other noteworthy observation was that three animals appeared to move with a somewhat shaking gait from eight to ten weeks after the commencement of the coffee feeding. When inspected by the veterinary officer he asked for close observations to be kept on them. However, this tendency decreased and was not noticeable after twelve weeks, when they moved about more or less normally.

During the last period the stock in both groups was mated and the coffee-feeding was terminated. The fertility of the two groups showed little difference in the proportion of fertile does from this batch of matings. In the control group eight produced litters and in the coffee ration seven, a difference of only one.

The diet had a direct effect upon thirst, and whereas the controls, receiving dry mash, drank 5·2 oz. of water daily, those receiving a 10 per cent replacement of fresh (moist) coffee dregs only drank 3·1 oz.

AIR-RAID DAMAGE AND ELECTRICITY SUPPLY

A FURTHER series of articles in the February issues of the *Electrical Review* record instances of the air-raid damage sustained by overhead lines, cables, and substation equipment, and the steps taken to effect repairs and restore supply (see also NATURE of February 7, p. 173). Although many engineers fully expected that overhead lines in the path of bomb blast would be levelled to the ground, actual damage has not reached a quarter of that anticipated. Admittedly, line conductors have suffered, and on pin type insulator lines, conductor binders have been severely strained, but it requires direct hits on towers or poles to interfere seriously with supplies. Bomb splinters, not blast, are generally responsible for the damage, stranded conductors showing definite evidence of having been severed. Wood poles appear to withstand blast better than steel ones, one large rural undertaking reporting that out of many near misses, only one wood pole was rendered unserviceable. Damage to pole transformers is rare and is usually only a slight puncturing of the casing.

As an indication of the amount of damage substation equipment can withstand, a switchboard which was blown right out by blast needed only minor wiring repairs. On another occasion a large outdoor transformer had its cooling tubes pierced at their lowest point by bomb splinters, and although the entire oil contents drained away the plant continued to function. At a certain static substation, a large bomb almost dived under the floor, which was split into four complete sections. Each of these, containing plant, was raised a foot and was at a different angle from its neighbour. The 6·6-kv. switchgear was found at an angle of 15° to the normal horizontal plane, many insulators were cracked and broken, all the trifurcating cable-box supporting lugs were torn away, and feeders were left hanging by their tails. The transformers were moved 2 ft. and lay taut on their cables, while the low-voltage floor-mounted switch-fuse gear was flat on its back with all the cable plumbing cracked. The roof was distributed among the plant, but the supply was maintained. A heavy bomb fell close to the side wall of another substation containing a 500-kw., 6·6-kv. to 460-v. D.C. glass bulb rectifier equipment. The substation was rendered nearly roofless and quite windowless and doorless, but the electricity supply remained intact. When the internal debris was cleared away it was found that the entire substation equipment had been moved at least 6 in. One rectifier bulb was destroyed but it had successfully cleared its A.C. and D.C. protection; the remaining three bulbs were unharmed and complete automatic control remained.

A safeguard employed by one undertaking against incendiary bombs on slate-roofed buildings is the placing of iron sheeting above the 2 in. of sand which is recommended for covering the rafters or flooring immediately below the roof. This sheeting absorbs the impact of the bombs, which otherwise has a tendency to disturb the sand. Substations appear to suffer little damage from fire, and it is not uncommon to find that they are the only part surviving of buildings destroyed by this means.

Ideas are being rapidly revised on the subject of fire danger to transformers. Instances are recorded of their having been charred, their insulation burnt off underneath, their oil having been boiling and actually burning, and their connecting cables being burnt off to stumps at the point of entry, but in each of these cases the apparatus has been salvageable.

Damage to cables has provided the largest source of instructive facts and problems. Although, despite the most severe bending, stretching, twisting and flattening, cables frequently remain in service, it cannot be taken for granted that an apparently sound length is unharmed. In many cases steel armouring has been found to have saved cables from damage, but it is advisable to carry out a pressure-test from at least the draw boxes on either side of the crater. Sometimes damage is caused to cable joints by vibration from nearby bombs, resulting in water entry. Pilot cables are often damaged although the main cables remain unharmed. Remarkable instances are reported of cables remaining alive after almost unbelievable damage. A 6·6-kv. cable cut by a bomb splinter remained in service for a fortnight, lying under debris without breaking down.

An indication of the depth of penetration that may be expected with some types of high-explosive bombs is provided by a chance hit on a 33-kv., 0·18-sq. in. submarine cable passing across a river mouth. This was damaged although the cable was some feet below the river bed and the water was several feet deep.

Restoration of electricity supplies after an air raid is very much simplified by having the area split up into sections, which, in a large area, may be self-contained and each have its own emergency repair gang. In repairing mains ruthless amputation of faulty sections is generally found to be the most successful course to adopt. Normally, cable saving has always been of paramount importance with distribution engineers, but under 'bomb conditions' experience has shown the necessity for quickly 'cutting and sealing' at the most convenient place for, generally, the craters quickly fill with water from damaged mains. Comparatively seldom, however, does the urgency of restoring supplies justify temporary cable repairs. While special emergency joints utilizing cold-filling compound have apparently justified their makers' claims, the general consensus of opinion is that they are not often warranted on the score of saving a few extra hours and should be used only when immediate recommissioning of the cable is essential. It must be emphasized that while some manufacturers claim their cold-filling joints are permanent, these joints are primarily for emergency use, and permanent repairs usually have to be carried out later. Failure to appreciate the necessity for very efficient mixing was, in fact, the cause of the breakdown of an 11-kv. joint after three months' operation. Another undertaking has come to the conclusion that the use of these joints is advantageous for cables of 33-kv. and higher, considering the saving of approximately a day and a half in the repair work worth while. In the bridging of cables across craters, many devices have been widely adopted, such as the use of scaffold poles as supports and the suspension of the cables temporarily on adjacent walls. Another scheme is the utilization of steel structures to support the cables temporarily while other parties requiring access to the crater attend to their work. These steel structures, which are generally covered with boarding to give the cable protection against stray splinters of anti-aircraft shells, etc., are erected rapidly and leave an almost clear space around for other work to be undertaken.

Practically all undertakings have now come to the conclusion that there is nothing to be gained by attempting anything in the way of actual repairs, apart from isolating bad sections of the system and restoring supplies to sound sections by means of alternative switching, while the raid is still in progress, except in very special circumstances. Apart from the unwarranted risk to personnel, little can be done until daylight. Much time and money is spent unnecessarily on having emergency repair gangs on duty throughout the twenty-four hours, and without any question of slackness it has been proved in practice that a much more satisfactory arrangement is to have the men standing by in their own homes and to call them up by telephone, or even by messenger, only when actually needed.

MARINE RESEARCH IN THE UNITED STATES

THE eight papers in the latest number of the *Journal of Marine Research** deal with all aspects of oceanography, physical, chemical, biological and bacteriological.

A. H. Woodcock continues an earlier inquiry into the effect of cold winds on a water surface. In shallow water the cooled surface water finds its way downwards by converging into small-scale streamings about 1 cm. across and several centimetres apart running parallel downwind. In vertical section a shallow surface stratum is broken up into a series of convection cells, and at the surface there are alternate convergent and divergent strips. In the open sea the small-scale streaming is present on the surface of the large waves, but there is also a large-scale convection mechanism with streams 50–100 ft. apart. On the small scale, lycopodium powder dusted over the surface falls at once into the linear pattern, and the gathering of Sargassum weed into parallel strips under the influence of a cooling wind is used as evidence of large convection cells.

Whitney describes measurements of the scattering of daylight in sea water. Whatever the altitude of the sun the light becomes more and more vertical as it penetrates, until it appears to reach an equilibrium distribution in which the light received from below is about half that received horizontally and roughly a fortieth of that from above. The depth at which such equilibrium is reached seems to vary between 5 and 30 metres according to the turbidity of the water. The measurements were made off the United States Atlantic coast and in a freshwater lake.

The waters off the United States Pacific coast are described by R. B. Tibby, who has measured the proportions of subarctic and equatorial waters in a broad coastal belt.

The first of the chemical papers deals with the $Na^{\cdot}/Cl'$ ratio in sea water. The relative concentration of all important ions in the sea is remarkably constant, but Robinson and Knapman, using a direct analytical method, have found a slightly higher ratio of $Na^{\cdot}$ to Cl' in the coastal waters of Puget Sound than in the open Pacific Ocean. The method will be of great value in studying small variations or continuous trends in the composition of sea water.

Sanderman and Utterback, measuring the radium content of bottom sediments off the west coast of America from Canada to the Arctic Ocean, confirm the earlier conclusion that deep sea sediments are richer in radium than those of the land areas, and that the concentration is largely confined to a very thin surface film. Their richest sample was one that was just skimmed from the sea bed, so fine that it took several days to settle. While admitting that the plankton is 100–1,000 times as rich in radium as the surrounding water they agree with earlier workers that the role of plankton as a carrier of radium to the bottom is likely to be negligible; their sediments from the regions of most abundant plankton were no richer than those from the most barren areas.

The biological papers deal mainly with the phytoplankton. W. E. Allen discusses the mechanism by which diatoms suspend themselves at levels favourable for their growth, or in some way keep contact with them. He considers their production of oils and gases, methods by which they can exert more or less friction on the surrounding water, and the possible effects of turbulent water movements. He believes that there are no reliable data for estimating the rate of sinking, laboratory methods lacking dependability for estimating the rates under complex sea conditions.

Gordon A. Riley summarizes his work on the plankton of the western North Atlantic in a diagram which illustrates the relationships between the phytoplankton and its environment. He makes an attempt to give algebraic expressions for the relative importance of the different factors. The equations need testing, and are likely to apply better to average than particular conditions, but they give some hope that the phytoplankton production will eventually be predictable with some accuracy.

A bacteriological paper is by C. W. Hock, who has isolated bacteria capable of decomposing chitin, the tough leathery substance found in both rigid and flexible parts of most invertebrates. The bacteria which attack this very inactive substance have been found in sea water, marine sands and muds, and in the intestines of several marine animals. Two species are described, both aerobic; ammonia-reducing substances and organic acids were among the products of decomposition.

G. E. R. DEACON.

FORTHCOMING EVENTS

Monday, March 30

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5 p.m.—Mr. C. E. N. Bromehead: "The Early History of Water-Supply".

Thursday, April 2

Town and Country Planning Association (in the Dome Lounge, Dickins and Jones, 224 Regent Street, London, W.1), at 1.20 p.m.—"Reconstruction and the Land".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Borough Electrical Engineer and Manager—The Town Clerk, Town Hall, St. Helen's, Lancs. (endorsed "Appointment of Electrical Engineer and Manager") (April 6).

Director of the Welsh Plant Breeding Station and Professor of Agricultural Botany—The Principal, University College of Wales, Aberystwyth (April 11).

Lecturer in Biochemistry—The Secretary, The University, Edmund Street, Birmingham 3 (April 25).

Engineer for the Sierra Leone Government Public Works Department—The Central Register (E. 370), Queen Anne's Chambers, Tothill Street, London, S.W.1.

Teacher of Physics in the Science Department—The Principal, South-West Essex Technical College and School of Art, Forest Road, Walthamstow, London, E.17.

Lecturer (man or woman) in Mathematics in the Junior Technical School for Boys—The Secretary, Woolwich Polytechnic, Woolwich, London, S.E.18.

Professor of Anatomy—The Secretary, University College, Cork.

COLONIAL DEVELOPMENT AND RECONSTRUCTION

THE importance of colonial development in relation to post-war reconstruction and Anglo-American co-operation has been widely recognized in several measures that have already been taken in furtherance of the new policy of colonial development and welfare outlined in the White Paper of February 1940, such as the establishment of the Leith-Ross Bureau and of the Hailey Committee. Lord Moyne has already been able to give an encouraging account of colonial development during the War, and in debates in Parliament dealing with labour questions and colonial welfare generally, suggestions for the further improvement of colonial administration, for example, by the appointment of a Standing Joint Committee of both Houses of Parliament, have been from time to time advanced. The International Labour Organisation devoted some attention at its conference in New York last October to labour problems in the Colonial Empire, and the place of colonial administration in Anglo-American policy was fully recognized before Japan launched her attack.

The recent reverses in the Far East have, however, brought colonial policy and administration into the forefront for urgent examination and drastic action.

The broadsheet on the "Future of the Colonies", which was issued early this year by Political and Economic Planning (P E P), is a suitable starting-point for the re-examination now demanded. The position in the south-western Pacific is only a special example of the general problem of colonial development, and a sound judgment on whatever mistakes in policy or administration may have been made in British Malaya cannot be reached apart from the broad background. Much of the defence and attack upon colonial administration in that area which have been developed seem to betray little sense of perspective, and to be unrelated to that broad strategic policy which is required both as part of our war effort and to implement the conceptions embodied in the Atlantic Charter. Five of the eight points of that Charter are directly relevant to the future of the Colonies, and while any elaboration of policies based on those generalizations presupposes the establishment of a durable peace and the creation of new international institutions, based on political realities, the initiation of such new forms of international co-operation is an indispensable part of the measures required to retrieve the position in the Far East.

In the development of tropical dependencies two problems are entangled : the need for development and the politically dependent status of the great majority of such dependencies. Both problems are resultants of their backwardness, cultural and economic, relative to the metropolitan countries, which has led to their being taken over as colonies by the more advanced nations. In considering the future of these areas, political, economic and social questions demand answers, and the fundamental problem is that of determining the relative emphasis and the desirable rate of change. We must determine not only the direction but also the tempo of advance.

Politically, we must first determine how far international regulation can be substituted for national possession, and, secondly, how best a movement towards responsible self-government can be encouraged. Economically, we must answer the questions how these areas can be developed so as to make their resources available to the rest of the world, and how the standard of living of the native peoples can be raised to enable them to play their part as markets for the products of other areas. Socially, we must determine first how to improve the health, the general relation of the individual to society, and the education and cultural development of native peoples, and secondly how Western techniques and ideas can be grafted on to an indigenous basis to secure social and cultural progress instead of disrupting native life.

Not only is it essential in tropical areas to discover the desirable rate of change, so that changes in one field may keep in step with other types of change, and assimilation and adjustment are possible, but it must also be remembered that such countries are only partly organized on a money economy basis, and most of their inhabitants have very low standards of life. Only where mineral resources are present have large financial returns in general been obtained, and many of these go directly to the metropolitan country. Disease, death-rates and the low educational level are other handicaps, and contribute to the persistence of backwardness, which is essentially a temporary phenomenon and should be regarded as an early stage in a far-reaching process of development, among the goals of which must be envisaged a high standard of life as well as self-government.

In regard to the political problem, it should be remembered that the foundations of European power in these areas were not in general laid by the deliberate action of Governments, but by the non-political action of traders. None the less, Colonies have always been a source of international friction, and, indeed, a special case of the friction between independent sovereign States of the modern type. Colonial friction cannot be abolished by any isolated treatment. As Schwarzenberger shows in his study of "Power Politics", Colonies form a special aspect of the relations of power and politics. The absence of a satisfactory moral basis for a dependent colonial empire, apart from the internal problem of meeting local aspirations for further self-government, would alone enforce the need, as part of a real world settlement, of developing a colonial system designed to eliminate the jealousies of the industrially advanced nations, to promote the development of tropical areas in the interests primarily of their own populations but also of the rest of the world, and to facilitate their progress towards self-government.

Of the concrete proposals towards that end, the PEP broadsheet dismisses as unsatisfactory the pooling of all Colonies under an international administration.

It is urged that the solution of the problem lies in the whole-hearted adoption by the colonial Powers of the principle of trusteeship, with all its positive and practical implications, including that of some degree of international supervision and regulation of colonial affairs. Implementing the trusteeship principle by practical schemes for economic and social development would remove the sources of political friction between the colonial and non-colonial Powers. The Colonial Development and Welfare Act of 1940 is, of course, a definite step in this direction, but large-scale international co-operation of various kinds will also be required, and other backward tropical areas, besides the Colonies in the strict sense, must be included in such schemes of combined social and economic development.

As further steps to abolish friction about the Colonies, and to promote greater uniformity in social and administrative standards in colonial areas, as well as to accelerate progress towards self-government and property, the broadsheet visualizes an extension of the mandate system into an international organization with an executive council, a reasonable central fund at its disposal, and an expert staff trained in an international staff college. Administration would remain in the hands of the existing colonial Powers, but a small proportion of technical posts should be thrown open at once to qualified men of any nationality, the selection to remain in the hands of the existing Power. This proportion should be gradually increased, and the process might be extended to administrative posts as men trained in the colonial section of the international staff college began to be available.

In addition, there must be guidance and supervision on the international level, and to secure international agreement on the interpretation of the trusteeship principle itself the promulgation of a Colonial Charter is suggested. This need affirm only the following points: (1) colonial dependencies are held in trust; (2) the primary aim of the trusteeship is to enable the dependencies to attain self-government as rapidly as possible; (3) the second major aim is the development of colonial territories primarily for the benefit of their own inhabitants; (4) the trusteeship is exercised jointly by all countries included in the international organization, but delegated so far as administrative responsibilities go to Powers with colonial experience; (5) no inherent or permanent inequality exists between races or peoples, and equal status and equal opportunity for all is a goal to be realized as speedily as possible; (6) all nations adhering to the international organization shall have equality of opportunity in the Colonies, subject only to the need for maintaining efficient administration.

The raising of minimum towards optimum standards will be best achieved by a series of international conventions, to be in general the concern of the International Labour Office, which should be strengthened by the foundation of a special Colonial Section. The establishment of a Colonial Commission of the international organization to secure a combination of efficient planning, advice and grants in aid of development is suggested, and this Commission should be provided with a small but highly trained international staff of experts and advisers. What is immediately required is the encouragement of sturdy, self-reliant local communities, with a liberal and increasing measure of self-government in economic and political affairs. As Lord Hailey has emphasized, not only in his great "African Survey", but also more recently in speeches in Parliament and elsewhere, the most urgent practical problem is that of raising the economic and social level of life in colonial areas.

This clearly means a revolution in our whole thought and attitude to the Colonies. The shift in emphasis from political to economic and social progress means more than economic planning in the narrower sense, the diversification of tropical economics and the raising of income and standards of life. It means close attention to the human resources, and particularly, well thought-out schemes of health and education. The importance of education in the broad sense in mitigating the bad effects resulting from the impact of white civilization on backward culture is not easily overstressed. Extension of experiments now being carried on by the Arts and Crafts Department at Achimota on the Gold Coast would lead naturally to the establishment of schools of social and economic survey and research, which, besides canalizing the enthusiasm and intelligence of the native *élite* as they become sufficiently trained, would provide, by carrying out field experiments, social and agricultural, a basis for the orderly development of social policy. Integration of higher education, including research, in European countries with that in the Colonies through large-scale interchange of personnel at various grades would be of particular value in preventing isolation and stagnation in the Colonies, and in stimulating interest at home in colonial problems.

The methods to be employed in furthering the general economic aim, however, must conform to three general principles. Each area should earn as much as possible towards building up its own essential services. Secondly, the maintenance of a proper standard of living should never be left at the mercy of local commercial interests or of the stresses and strains of world economic forces; a basic minimum standard should be guaranteed, however long it may be before the area can be developed to become self-supporting. Thirdly, all external commercial enterprise must operate to the benefit of the local population.

As to the machinery of tropical development, the broadsheet suggests that a Colonial Investment Board should be attached to the International Colonial Commission to influence and guide private finance into the channels most suitable for achieving colonial development. In addition to Government administration, co-operative producer agencies, such as the Empire Cotton Growing Corporation in the Sudan, and marketing agencies associated with international control schemes which already function, two further types of large-scale development agencies are envisaged: international public concerns, operating for profit under licence, and regional development agencies, not operating for profit. The former might be started where a local surplus is available and can find an external market, and it might take various patterns subject to welfare and conservation regulations approved by the Colonial Commission and to limitations on profits.

Regional development agencies, on the other hand, will be required in those numerous regions which require large-scale development before they attain a level of economic activity at which commercial profit can be expected. Their problem is as much social as economic, and involves the transformation of every aspect of life. When established they should be under international supervision, and apart from this their functions would closely resemble those of such a body as the Tennessee Valley Authority. Similarly, wherever one of the main products of a territory is controlled by an international commodity control scheme, a local producers' organization, with Government participation, will be required to represent the territory and to arrange for proper marketing facilities.

On the necessity of planning development in all backward areas on a long-term basis, to achieve smooth working, there can be no reasonable doubt, and the broadsheet equally endorses the "African Survey" in its insistence on the need for adequate survey and research as a pre-requisite to development in almost every field. Also it sees in the regional development of the equatorial territories of Belgium, Britain and Free France, Anglo-American co-operation in the Red Sea area and the Persian Gulf, and the Supply Councils for the Eastern Group, the Middle East and the Pacific Areas, a tendency towards the grouping of separate territories into larger units capable of supporting the expert staff required for such developments as are suggested. Besides this, it is essential that with the extension of international co-operation, and the delegation of more power and responsibility to administrators on the spot, the Colonial Office must include a section for the framing of broad policy.

It is no disparagement of British colonial achievements in the past or of the new policy represented by the White Paper of February 1940, to suggest that one good result of the defeats in Malaya and Burma may be a greater readiness to recognize that in the field of colonial policy and administration Great Britain has much to learn from the experience of others in the same field, and that in the pooling of experience the contributions will come not from one side alone. The breakdown of any such reserve is essential in the pooling of ideas, in participation in joint regional schemes, in projects for survey and research, in association on the International Colonial Commission and other ways by which the colonial Powers could rapidly establish a common policy of material, political and cultural development.

The bitter experiences of the East Indies may indeed result, not in useless recrimination or invidious comparison between Dutch and British practice, but in a close contact and pooling of experience which will enable us to construct a new regional order. Already there are signs that the Colonial Office is alive to many of the issues involved. The memorandum submitted to the International Labour Conference, Major Orde Browne's report on labour conditions in West Africa, the establishment of a special department on Labour and Welfare, and of a Labour Advisory Committee, are all indications of a new outlook and a greater readiness to learn from the experience of others, whatever doubts may sometimes be entertained as to the extent to which the new outlook has found expression in the field. Moreover, this is not a matter which is the concern of Great Britain alone. Apart from the great help which the United States can undoubtedly give generally, particularly in such areas as the West Indies, to implement a far-reaching constructive colonial policy, the co-operation of the British Dominions is also essential.

The problems of the Colonial Empire were discussed in two articles in *The Times* of March 13 and 14 by Miss Margery Perham. It is impossible to summarize them here; they should be read and studied carefully. Some points she raises have been taken up in correspondence by Dr. Raymond Firth and by Lord Moyne. Dr. Firth points out that for more than a decade anthropologists, educationists, historians and others have been amassing data relating to the Colonies, and that they have stressed the bad effects of labour migration, the economic difficulties of the native peasantry and the lack of educational opportunities. He envisages more adequate training of administrators, whether native or white, in economics and other social studies, recognition of the importance of science in coping with all aspects of colonial life, and wider understanding of colonial questions by the people of Great Britain. Lord Moyne discusses in particular the financial disadvantages under which colonial administration has functioned, condemning in particular the system whereby the white officials are, in effect, dependent on local budgets for salaries and pensions, so that the poorer Colonies, which need the ablest men, are automatically unable to employ them.

The dominant need at the present moment is for the examination of policy and administration in the remaining Colonies and Dependencies with the determination to eradicate swiftly and ruthlessly any mistakes or weaknesses revealed in the light of recent experience. We must also initiate without delay whatever measures may be required to capitalize their good will and moral as well as material resources in the service of freedom, and in the furtherance of a colonial policy designed to eliminate friction between the great Powers over colonial questions and enable each major colonial region to develop its own culture with the assistance of the science and thought of the Western Powers. If we can bring to this task the necessary magnanimity, vigour of mind, vision and firmness of purpose, we shall find that once again our policy and its execution serve both the immediate war needs and the furtherance of those changes designed to secure an enduring peace. Nor should it be forgotten that the achievement of such aims and the removal of the frustration which is the key-note of the dissatisfaction felt in the Colonies to-day, both by the advanced minorities and by recruits in the colonial service, involves a much wider and intelligent interest in colonial affairs by the people in Great Britain. Scientific workers who, as Lord Hailey's great survey has shown, have so large a part to play in colonial development, must not be backward in the work of educating public opinion that is involved.

THE THREE NEGATIVES OF THERMODYNAMICS

The Nature of Thermodynamics

By Prof. P. W. Bridgman. Pp. xii+229. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1941). 20*s*. net.

THE position of author and reader in this challenging book are those of two students of thermodynamics who have mastered conventional thermodynamics, and, having attained some degree of maturity in applying it, agree to confide in one another their various doubts and difficulties. In a pleasantly informal way, Prof. Bridgman discusses a variety of situations to which the easy application of thermodynamic reasoning is far from obvious; and the reader *may* end by becoming a sceptic. Nevertheless, the broad principles of thermodynamics emerge from their ordeal, on the whole, better than one feared. The attitude of the book is the reverse of complacency; it never says "physics teaches . . .", and it will have done good in showing that orthodox positions are never incapable of criticism.

The author's general purpose is the attainment of "understanding", and with this object he rejects any precise, logical, postulational formalism in favour of discursive argument. His topics are the three primary concepts: temperature, energy and entropy. But his procedure is not to treat them as indefinable concepts (cf. Bryan's treatment of energy in his famous "Article"), but to apply always the 'operational' method, that method which consists in defining quantities only through the material processes by which they can be measured. The method in effect originated in the British school of philosophy of Locke and Hume, but in modern days takes its inspiration from Einstein, who applied it with such brilliant success to the previously undefined concept of simultaneity. It has been developed at length by Prof. Bridgman in an earlier work.

The three thermodynamic notions above-mentioned are connected with three well-known negative statements of operational character—"postulates of impotence" as E. T. Whittaker has recently called them. Temperature is connected with the *inaccessibility* of certain states of a body from other states as a starting point, when the body is adiabatically enclosed. Energy and entropy are connected with the *impossibility* of constructing certain types of 'perpetual motion' machines. From these statements, the concept of a measure of temperature and the two laws of thermodynamics may be isolated. Prof. Bridgman truly remarks, in this connexion, that thermodynamics smells of its human origin: adiabatically walled bodies, and heat-engines, are constructions that do not "occur in nature", any more than the triangles of geometry. They are none the less proper subject-matter for theoretical physics.

Prof. Bridgman's operational method as regards temperature is akin to the above negative postulate. He shows that a variable (the "temperature on an empirical scale") is necessary to complete the description of the state of a body in addition to a set of independent mechanical variables equal in number to the degrees of freedom possessed by the body when in 'thermal' equilibrium with a given large body. The author says much to clarify the foregoing rough paraphrase, since the 'thermal' in thermal equilibrium needs explanation, and moreover we eventually use some *mechanical* variable such as length or volume to measure temperature. I am scarcely convinced that a 'heat-blind' person would gain a clear picture of temperature from Prof. Bridgman's account; but probably this would require that postulational treatment which the author is at pains to avoid.

With regard to the next negative, it is remarkable that Prof. Bridgman scarcely mentions the question of what is meant by the 'mechanical equivalent of heat'. We cannot test the First Law by means of the author's "surface sentries", until we have a value for J; yet we apparently cannot determine J without assuming the truth of the First Law. It is from the *proportionality*, of course, of heat gained to work lost that the idea of conservation of energy originates. But the author never says so. Instead, he spends much time on the hypostatization of energy, a tendency which I can only deplore. The author seems (in spite of disclaimers) to regard energy as having traceable identity: if it disappears at A, and appears at B, he is anxious to locate it on its way from A to B, and he therefore attempts to measure its *flux*, and to resolve the latter into a density and a velocity. One feels that Prof. Bridgman's engaging illustrations—the problems of the bent bar in motion (p. 45), of the moving rough block (p. 48) and of the gravitationally attracting spheres which are held apart by rigid connexions during their displacement (p. 107)—involve difficulties only because he insists on hypostatizing energy. Actually we know nothing of energy directly. To the operational method, energy is only known through performance of mechanical work (a more elementary notion than energy): when we perform work, either we create heat or we store up the power of securing work to be done for us in future, and thermodynamics gives the name energy to a certain linear function of the two which remains constant. The author appears to forsake the principles he is expounding when elaborating his ideas of energy-flow. He hypostatizes entropy similarly in its turn, but here the boot of criticism finds itself on its proper leg, for the student's usual difficulty is to think of entropy as a *thing* at all.

Prof. Bridgman repeatedly returns to the question of whether the macroscopic methods of thermodynamics or the microscopic methods of statistical mechanics are the more fundamental. He points out that all the basic microscopic variables are defined in terms of operations the practicability of which is derived from our large-scale experiences. He concludes that logically the thermodynamic method is the more fundamental. "The complete confidence of most physicists in their atomic analysis . . . overlooks the essential fact that logically the microscopic nas its origin in the macroscopic. Any suspicion of che adequacy of our macroscopic analysis should at nce arouse suspicion that our microscopic analysis s also inadequate." This is well said; in physics, to e iconoclastic of the macroscopic is to be defeatist. It may be mentioned that Prof. Bridgman is extremely appy in his account of the deficiencies of Maxwell's lemon.

In conclusion, it may be remarked that the laws f thermodynamics are not to be confused with the phorisms in which they are sometimes supposed to be xpressed. To say that the energy of the universe is onstant, or that its entropy increases, are operationlly meaningless phrases. We can only speak of the nergy of the universe at an instant when we have et up a standard of simultaneity; as this universe f ours contains, apparently, *motion* on such a large cale, simultaneity in the large is a matter of convention and of the scale of time adopted; hence to add together the energies of the separate parts of the universe at chosen instants is a purely conventional process; moreover, the universe (in my opinion) is probably not finite in number of particles. The difficulties with regard to energy are accentuated if we try to speak of the entropy of the universe, for to show that it increases we should have to compare entropies at two separate 'instants', and the simultaneity trouble crops up again worse than ever. It must be said that Prof. Bridgman adopts an exceedingly naïve cosmology in discussing the energy and entropy of the whole universe. Nevertheless, it is pleasing to find that he insists that before one can even attempt to speak of the energy of the universe, it is necessary to contemplate the separation of the universe into at least two parts, one of which contains the observer and his apparatus, and the other is the seat of possible energy transformations. I rejoice in this for the personal reason that some years ago I was castigated by a referee for pointing out a similar situation with regard to entropy: to measure the entropy change consequent on an 'irreversible' process, it is necessary to undo the process *reversibly* by heat transfers to and from a portion of the universe *external* to the seat of the irreversible process in question. Operational tests of the famous energy and entropy aphorisms of Clausius are thus most awkward. Prof. Bridgman's exposures of all the far-flung consequences of the operational method are highly stimulating.

E. A. Milne

THE RANDOM ELEMENT IN TIME SERIES

The Variate Difference Method

By Gerhard Tintner. (Cowles Commission for Research in Economics, Monograph No. 5.) Pp. xiv+175. (Bloomington, Ind.: The Principia Press, Inc., 1940.) 2.50 dollars.

NEARLY all time series, whether possessing trend or not, exhibit fluctuations of a more or less irregular kind. One of the first questions to be considered in analysing such series is how much of the fluctuation can be ascribed to purely random effects —random in the particular and important sense that a value at one point is independent of values at other points in the series. From the very nature of random variation it is impossible to calculate the random component at every point, except in the form of a residual which is left over when the systematic element has been abstracted; but it is possible to estimate the variance of the random element for the whole series on certain broad and plausible assumptions.

If a time series is differenced k times, the variance of the random element in the resultant series inincreases rapidly, being $(2k\,!)/(k\,!)^2$ times that of the original. On the other hand, the systematic element is reduced, or at least does not increase to the same extent, unless it is of very short period. If, therefore, a given series is differenced, and its variance divided by the factor $(2k\,!)/(k\,!)^2$, the result should tend to the variance of the random part of the original series. The elimination of systematic effects by differencing is the basic idea around which the theory of the variate difference method is built.

The method appears to have been used for the first time by Poynting in 1884 in a study of the relationship between wheat prices and silk—and cotton—imports into the United Kingdom. Since that time it has engaged the attention of many writers, not always favourably, and the mathematics of the subject have been worked out very fully by Prof. Oskar Anderson, whose treatment is followed by Prof. Tintner fairly closely.

This book is an excellent account of the whole subject and can be thoroughly recommended. Tintner explains the technique of the variate difference method in great detail but has relegated mathematics to notes and appendixes, with the result that the non-mathematical reader can assimilate and apply the method without being bothered by theoretical detail, but on the other hand with a full understanding of what he is doing.

There is one important point arising out of the interpretation of results given by the method which one would like to have seen brought into greater prominence. In economic time series the random variance is often found to be a surprisingly small proportion of the total variance of the series, frequently only about 10 per cent and sometimes as low as 5 per cent. The natural inference would be that the remaining 90 or 95 per cent is systematic and hence may be predictable. But this is not necessarily so. The variance shown as 'random' by the variate difference method is attributable only to effects, comparable to errors of observation, which do not lag from one year to another. An economic disturbance may be random in the sense that it is casual and unpredictable, but once it has occurred it may affect subsequent years, and if it does the variations in successive years are no longer independent. The result may be either to increase or to decrease the variance given by the variate difference method. This type of correlation between successive years is not uncommon and is an overriding difficulty in the interpretation of the results given by variate-differences. There are other points which have led authorities such as Udny Yule, Bowley and Persons to doubt the usefulness of the method; but Prof. Tintner gives full references to these criticisms, and his exposition of the subject is well worth a careful reading by anyone interested in the baffling subject of time series.

M. G. Kendall.

MIDDLESEX PLACE-NAMES

The Place-Names of Middlesex, apart from the City of London

By J. E. B. Gover, Allen Mawer and F. M. Stenton, with the collaboration of S. J. Madge. (English Place-Name Society, Vol. 18.) Pp. xxxiv+238. (Cambridge: At the University Press, 1942.) 18*s*. net.

The appearance of another volume of the English Place-Name Society is at all times welcome, but in these days more so than usual. The book, but for special difficulties easy to be imagined, would have dealt not only with the County of Middlesex, but also with the City of London. With regard to the latter some of the necessary unprinted sources had become unavailable, and not everything which the editors desired in the case of Middlesex could be produced from "places of safety". Add to this that the invaluable help of Prof. Ekwall, through the exigencies of war, was lacking, and it will be seen that certain additions to what is now published may possibly be forthcoming in due time. But when all is said, the book is a mine of information, and is written with the trained judgment and precise scholarship which the names of its editors and compilers guarantee to us. A most essential point; for the study of place-names has a fatal fascination for the man in the street; he rushes in where the learned will suspend judgment, and their cautious approach to such household words as Piccadilly, Pimlico and Soho is rather in the nature of a red rag to him.

The name of Middlesex—the province of the Middle Saxons—is somewhat of a disappointment in itself, implying a much more important territory than the little county we know, a county, moreover, which while witnessing to the early stages of the Saxon settlement never became prominent or produced any of the great men of the time. So that where Saxon personal names survive, as in Kensington, Islington or Ealing, we know nothing of Cynesinge, Gisla, or Gilla, nor are the more interesting survivals of tribal names much more enlightening. A thrill is, however, to be obtained from the cryptic Gumeninga Hergæ, preserving the memory of a heathen shrine where now stands that famous landmark the spire of the church of Harrow-on-the-Hill.

The general impression given is of a district of farmland and woodland, full of small settlements the owners' names of which, where early documents have come down to us, are to be verified now and again; but where no records earlier than the twelfth or thirteenth centuries exist, have been altered out of recognition, and can only be guessed at. The physical features of the district, which are not striking, account for another batch of place-names, and tend inevitably to repeat themselves, as in South African place-names, of to-day. There are obscurities here, as when names implying chalk, in a district where no chalk occurs, have to be considered, and the traditional derivation of Chelsea, as a "port where lime is landed", will not survive linguistic tests, and is here suggested to be due to "folk-etymology". Such popular explanations of place-names are disappointing, and instinctively avoided, as an easy way out, by the scholar. A later series of names, the origin of which is either humorous—as Eel-pie Island—or contemptuous—as the Isle of Dogs—come into the same unsatisfying category, and there is finally the list—only too long—of names for which no adequate explanation can be given. Among these it is sad to find that inevitable attraction, Cold Harbour, here dismissed as "of no particular archæological significance"—almost as much of a shock to the interested public as is the Charing of Charing-Cross, which long precedes Queen Eleanor, and refers to the bend which the river takes at this point. Nor can we do other than regret that Horace Walpole's Strawberry Hill, so redolent of its period, must own its descent from a house built by a retired coachman and dubbed by his candid friends Chopped Straw Hall.

The lists of street names given under districts rest on a much firmer footing, as is natural, and are invaluable as a record of recent development, the memory of which soon fades.

The book ends with a list of the elements, apart from personal names, found in Middlesex place-names. Only four of these, all river names, come down from the times before the Saxon invasions, and at the other end of the story are three of French origin. There follows a list of Saxon personal names, and a solitary Scandinavian; then field and minor names, and an appendix on Saxon charters of Hendon, Hampstead and Westminster. Once more, a mine of information

Charles Peers.

Statistical Dictionary of Terms and Symbols

By Dr. Albert K. Kurtz and Dr. Harold A. Edgerton. Pp. xii+91. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1939.) 12*s.* net.

THE authors have collected their data from a number of current text-books and periodicals, and have been aided by an advisory council comprising some of the best-known American statisticians. Only definitions and occasional illustrative comments are given. This is in no sense a source book like Mulhall's famous "Dictionary of Statistics."

There is undoubtedly scope for a book of this kind, if only to help in standardizing nomenclature. Indeed, one of the most striking things brought out by the present work is the variety of names applied to the simplest statistical concepts. No fewer than eighteen synonymous terms are given for the normal distribution. For the figure known to English statisticians as the "scatter diagram" there are a dozen equivalent terms of varying degrees of cacophony, etymological impurity and sheer inaccuracy, such as "scatterplot", "scattergraph" and "double frequency table". The authors have been very chary of exercising the lexicographic prerogative by condemning any of these expressions as bad usage.

There are errors of both commission and omission in this book. The Gram-Charlier Type B series (p. 70) is not the same as the Poisson series; Bayes' principle (p. 16) is not the same as Bayes' theorem; the tetrachoric functions (p. 176) are not the same, except for sign, as Hermite's polynomials (which, by the way, are due to Tchebycheff, not to Hermite); the function usually denoted by t is not the ratio of a statistic to its standard error (p. 174). Of the five definitions of "error" on page 56 the first is "the observed value of a variable minus the true value. Not to be confused with deviation from the mean", and the fifth is "same as deviation from the mean". No doubt both usages exist, but the caution against confusion reads rather oddly. Among the omissions may be noted the absence of definitions of serial correlation, distributed lags, orthogonal polynomials, conditional statistics, Latin squares, random sampling numbers, divided differences, Edgeworth's translated frequency curves, cumulants and characteristic functions.

A dictionary of this kind will be generally useful and it is to be hoped that subsequent editions will see the incorporation of the many improvements which are possible.

M. G. KENDALL.

In Search of Northern Birds

By Seton Gordon. Pp. 224+16 plates. (London: Eyre and Spottiswoode (Publishers), Ltd., 1941.) 15*s.* net.

SETON GORDON has again recaptured the air and charm of the lonely hills and islands of the north, and in his usual inimitable style. Few naturalists have described these solitudes so often and so pleasantly. The descriptions of well-loved hills and islands are interspersed with observations on birds and beasts and flowers.

It is a wide range that Seton Gordon embraces in his search of these fastnesses, and his notes on winter-day wanderings have perhaps a special value to most of us who only know these places in summer. He takes us from Lambay Island (Rechru) in the Irish Sea, and from the Pembrokeshire Islands, through the Hebrides (with a note on the little Northumbrian Island of Coquet) as far north as Iceland. On the north coast of Iceland, near Akureyri, he saw birches twenty feet high. At Lake Myvatn the flies drive even the hardiest fisherman to abandon the splendid trout-fishing. In the Westmann Islands he reminds us of the gannet colony at Sulnasker, and we can add that we have seen gannetries also on the neighbouring islets of Geldungur, Hellisey and Brandur, making a pretty large colony of probably four thousand breeding pairs.

Back in the Cairngorms, Seton Gordon asks how is it that moss can survive under snow for perhaps more than a year. He tells us that at the present day the marten still survives in the far north-west of Scotland, while the wild cat is not in danger of extermination.

R. M. L.

Electric Power Stations

By T. H. Carr. Vol. 2. Pp. xv+440. (London: Chapman and Hall, Ltd., 1941.) 32*s.* net.

THIS book, which deals with the electrical equipment of power station plant, is a companion volume to the author's earlier work on the mechanical side of the subject, and the two together constitute a very informative survey of modern station practice. The subject arrangement of the present volume betokens the authority with which the author writes and it covers alternators, condensing plant, feed-heating and water-treatment plant, transformers and reactors, switchgear, cabling and cables, oils, station auxiliaries, electrical protective equipment, station lighting, commissioning and testing of plant, station organization, station costs, and fire fighting and A.R.P.

Broadly, the book embraces considerations of design, construction and operation, and it contains numerous line and half-tone illustrations and detailed calculations where desirable. Many tables are included and a bibliography is given at the end of each chapter to facilitate further study.

As Sir Leonard Pearce says in his foreword, the book will be valuable in enabling specialists to keep contact with branches of engineering other than their own.

Algebraic Solid Geometry

An Introduction. By S. L. Green. Pp. vii+133. (Cambridge: At the University Press, 1941.) 6*s.* net.

THIS little book, based on courses of lectures given to students of Queen Mary College, London, may be regarded as an attempt to reduce the subject of algebraic solid geometry to a minimum. There are six chapters, dealing respectively with co-ordinates and direction-cosines, the plane and straight line, the sphere, the central quadrics, the paraboloids and the cone. The number of diagrams is only fourteen, which is scarcely sufficient. The second diagram has to serve for two different theorems, and does not show all the points mentioned in them. The examples include several from recent examination papers of the University of London. The general impression conveyed by the book is that the author's primary object was to make the subject as easy as possible, but that he has been handicapped in this by having to consider also the need for economy in paper.

POST-WAR AGRICULTURAL RECONSTRUCTION

By G. V. JACKS
Imperial Bureau of Soil Science

THE Division for the Social and International Relations of Science of the British Association held a Conference in London during March 20–21 to discuss problems connected with the post-war reconstruction of agriculture in Europe. Representatives of most of the occupied countries attended, and many addressed the Conference. A remarkable unanimity was evident in the diagnoses of the causes of pre-war agricultural troubles and in the formulation of the desiderata of reconstruction. All agreed that the best hopes for the future lie in the development of small-scale peasant farming concentrating primarily on livestock, fruit and vegetable production, this being a type of agriculture that would best serve to absorb the abundance of available labour, to raise national standards of living and of nutrition, and to enable European economy to play a more harmonious part than hitherto in world affairs.

At the first session, which was opened by Sir Richard Gregory, President of the Association, the need and aims of agricultural reconstruction were discussed. Sir John Russell, from the chair, said that one of the most immediate needs that will have to be satisfied is the provision of fresh seed and livestock for the devastated regions, and he suggested that schemes for collecting supplies should be initiated forthwith, particularly in North America, where the wide range of soils and climate enable all the kinds of seed required to be propagated. Sir John, like all the speakers, sees the best prospects for the successful rehabilitation of European agriculture in a greater production of 'protective' foodstuffs at the expense of cereals.

Mr. Kenneth Brooks gave an account of the European relief activities of the Society of Friends after the War of 1914–18. From the experience then gained he drew four main conclusions: (1) that it is impossible to separate relief from rehabilitation; (2) that short- and long-term policies in agriculture must be developed concurrently; (3) that international co-ordination of monetary and fiscal policy is essential; (4) that the quality of human sympathy in the administrative personel is at least as important as professional qualifications. A paper by Mr. Mikolajczyk, Deputy Prime Minister of Poland, indicated, by reference to present conditions in his country the immensity of the difficulties which will confront relief workers after the War.

Dr. B. Cubrilovič, approaching the subject from the economic point of view, maintained that a planned international economy with human welfare rather than profit as the objective must form the basis of any scheme of permanent reconstruction. Agriculture cannot be planned apart from industry, nor can a plan succeed which does not admit that the welfare of Germany is complementary to that of eastern Europe.

An account of predominantly small-scale farming in a densely populated country was given by M. L. Borremans, from Belgium. Under German occupation, grain production is being excessively stimulated at the expense of livestock and mixed farming. There will be urgent need after the War to restore the intensive production of protective foods and livestock, and to re-develop the processing industries.

At the second session a discussion on economic problems was opened from the chair by Mr. F. L. MacDougall, who referred to the work of the League of Nations Nutrition Committees, which are now taking up problems connected with post-war reconstruction. He feels that the basis of reconstruction should be the attainment of the four freedoms of the Atlantic Charter, and in particular freedom from want. The most serious nutritional deficiencies have occurred in those countries producing cereals for export. Post-war Europe will require an immense expansion of livestock farming; wines and fruit might advantageously replace wheat as the main export of south-eastern Europe. He thinks that a regional authority, on the lines of the Tennessee Valley Authority, operating independently of political boundaries and with wide powers to integrate riparian activities and co-ordinate them with other forms of production, might be set up in the Danube basin. But the basis of any such scheme must be adequate nutrition, the attainment of which is not precluded by any natural factor from any European country.

Dr. D. Mitrany advocated the cause of the peasantry against the views of the classical and Marxist economists, who affirm that the peasant is an anachronism, on the assumption that the basis of agricultural evolution must be a steadily increasing demand for wheat and other large-farm crops with the growth of industrialization. But since European wheat can never compete successfully with wheat grown extensively in the newer countries, emphasis in Europe is swinging from quantity to quality production, that is, to types of farming pre-eminently suited to peasant proprietorship. The Nazi aim of European self-sufficiency would mean the death of the peasant; the alternative—a higher nutritional standard and co-operation with overseas grain producers—could be achieved by a greater development of mixed peasant farming. Mr. N. Barou described the development of collective farming in the U.S.S.R., where the small private holdings held by the workers have been found to afford a necessary outlet for the individualism which is as characteristic of the collective farmer's nature as it is of that of the peasant.

Dr. R. Bičanič said that over-population of the land in eastern Europe has resulted in poverty, exploitation, excessive subdivision of holdings and consequent inability to effect any agricultural improvements. He believes the net effect of the War will be to increase over-population. Suggested remedies include the allocation of more land to the peasants and its more equitable distribution, intensification of mixed farming, the development of rural industries and the undertaking of public works on a large scale. There is need for great speed in making these changes, which will produce revolution unless they are made as part of a carefully planned economy within an international frame.

Mr. P. Lamartine Yates took Danish agriculture as an illustration of how a large population can be supported on naturally poor land at an exceptionally high standard of living. He associated Danish rural prosperity with the high proportion of intensively farmed arable land together with a livestock population much greater than could be fed off home-grown fodder, and in particular with the high level of education of the farmers. The advancement of agriculture in more backward countries depends as much on broadening the basis of education and raising the standard of intelligence of the people as on any of the economic and agricultural remedies mentioned at the Conference.

The future betterment of European farming was discussed on the second day at sessions presided over by Mr. A. J. Drexel Biddle, the American Ambassador to the occupied countries, and by Sir John Russell.

Miss Margaret Digby recapitulated the causes of agricultural backwardness advanced by speakers on the previous day, and emphasized the military reasons for State policies aiming at keeping an excessive population on the land. She called for a reconstruction programme based on high nutritional standards, more efficient farming, freer trade within a planned international economy, freer movement of populations and a wide development of rural industry.

Dr. L. Feierabend believes that agricultural evolution in Europe must be in the direction of small, individually owned farms working co-operatively. He distinguished clearly between co-operative and capitalistic farming. The primary aim of a co-operative society should be not the making of profits, but "the support of the business of its members", that is, the improvement of the land. He agreed with other speakers that a high standard of education is a necessary element in the success of any co-operative scheme. Mr. S. Malessa stressed the interdependence of agricultural and industrial planning. The problem of rural overpopulation can only be solved by industrial planning to absorb the surplus.

Dr. L. Dudley Stamp outlined the geographical factors determining and limiting the types of crop production feasible in Europe, and advocated planning on a regional rather than on a political basis. Dr. J. Krnjevič described the political emergence of the Croatian peasantry, comprising 90 per cent of the population, through the cultural activities of the Croat Peasant Movement.

Dr. J. Hammond gave an account of artificial insemination, which several speakers thought could play an invaluable part in restoring the quality and quantity of livestock. Mr. A. Fjelstad dealt with practical problems of the small livestock farmer in Norway, and Mr. P. H. Pedersen with practical aspects of milk production in Denmark. Both the last two speakers stressed the importance of effective co-operation in small-scale, intensive farming.

QUANTUM THEORY AND DIFFUSE X-RAY REFLEXIONS

By G. D. PRESTON
National Physical Laboratory

THE origin of certain anomalous X-ray reflexions, that is to say, intensity maxima the presence of which cannot be explained by the usual diffraction theory, has recently been the subject of investigation in many laboratories. Some account of the work carried out in Great Britain was given at a discussion held in London on February 6, 1941, and a review of this discussion appeared in NATURE of April 19, 1941, p. 467; a fuller account has been published in the *Proceedings of the Royal Society*, A, 179, 1–102, 1941. The progress made in the investigation of this interesting subject in India has recently been reported in the *Proceedings of the Indian Academy of Sciences* of October, 1941, which is wholly devoted, to quote from the cover, to a "Symposium of papers on the Quantum Theory of X-Ray Reflection and the Raman Reflection of X-Rays in Crystals". This description of the subject-matter reflects very clearly the difference in the interpretation of the phenomena which exists between French, American and British physicists on one hand, and the group of Indian physicists at Bangalore working under the leadership of Sir C. V. Raman on the other.

Before considering the nature of this difference of interpretation, it will be convenient here to indicate the scope of the papers presented to the symposium. Sir C. V. Raman contributes two papers on the theoretical aspect of quantum X-ray reflexion, and in collaboration with Dr. P. Nilakantan provides experimental confirmation from a study of diamond, a crystal the reflexion from which is also discussed by P. Rama Pisharoty. Dr. C. S. Ventakateswaran contributes six papers; one illustrates the change of intensity of the anomalous reflexions at low temperatures and the remainder deal with the patterns formed by rock salt, naphthalene, benzophenone and hexamethyl-tetramine. Benzil is investigated by R. V. Subrahmanian, and aluminium and calcite receive attention from Bisheshwar Dayal, P. Nilakantan and P. G. Nayar. This brief outline of the field covered on the experimental side will serve to show that, whatever differences of opinion exist as to the origin of the reflexions, the phenomena investigated are in fact the same as those studied in France by Laval, in the United States by Wadlund, Zachariasen and Siegel, and in Great Britain at the Royal Institution and the National Physical Laboratory.

It is perhaps worth while here recalling the salient features of the effects observed. When a single crystal of, say, aluminium, rock salt or sylvine is mounted in a beam of X-rays which traverse the crystal in a direction parallel to a cubic axis, a Laue photograph is obtained if the beam consists of 'white radiation'. In addition to the Laue spots, there appears on well-exposed plates a number of streaks, running through the Laue spots, which apparently should have no business there. When the composite X-ray beam is replaced by a monochromatic beam, the usual theory of crystal diffraction tells us that no reflexion should be observed unless the crystal is orientated in a particular way. In general, the condition for reflexion will not be satisfied, except by a lucky accident, and a blank photograph should result. However, in fact, reflexions are observed. They are faint, but have the symmetry proper to the crystal axis in which the incident X-ray beam lies. Examples have been published in the pages of NATURE (143, 76 (1939); 147, 467 (1941); 148, 112 (1941)). It is this background of 'non-Laue' diffuse reflexions that is attracting the attention of X-ray crystallographers. To what is it due?

There appear to be several possible answers to this question. The most comprehensive is perhaps to say that the diffuse background arises as a direct result of departures from geometrical perfection in the crystal architecture. A periodic flaw, a regular precipitation of an impurity such as produces a Widmanstätten pattern, and the temperature vibrations of the atoms are all possible and probable causes. It is the task of the experimenter to devise means of identifying the different causes so that use may be made of the machinery provided by the mathematician to enlarge our knowledge of the solid state. Those features of the background reflexions which occur in crystals of pure substances, so that flaws and chemical segregation are excluded from consideration, are evidently of great importance. There is general agreement on all sides that this background is due to movement of the atoms or molecules of the crystal from their positions of perfect geometrical alinement. The differences of interpretation arise in assigning the cause of the movement and in the mechanism of X-ray scattering. In Great Britain and in the United States, the whole effect is ascribed to the thermal vibrations of the crystal lattice. Just as the Laue and Bragg reflexions are a picture of the static geometry of the crystal, so the diffuse background is a picture of the dynamic vibrations of the crystal. The undisturbed crystal can be regarded as a medium in which the density varies periodically in space, and the effect of the temperature vibrations is to superimpose a spectrum of much longer elastic waves on the natural periodicity of the crystal. The whole crystal then diffracts as a unit and the resulting pattern consists of the usual Laue reflexions plus a background due to the motion of the atoms.

The point of view adopted by the Bangalore group of physicists is rather different. In places I find it obscure and can only hope that the following brief paraphrase of their views does them no injustice. To begin with, the quantum aspect of the interaction of X-rays with the atoms of the crystal is emphasized. The radiation scattered from an oscillating atom is stated to consist of three components, the amplitudes of which depend on the amplitude of oscillation of the atom, and which differ in frequency. The first component, which gives rise to the normal reflexions, has the frequency ν of the primary X-ray beam, while the other two have frequencies $\nu \pm \nu'$, where ν' is the frequency of the atomic oscillation. The frequency change is unfortunately too small to be measured directly.

The atomic oscillations which produce the frequency modulation are supposed, according to Raman, either to arise as a result of direct excitation by the incident beam or to be present as thermal vibrations. The existence of the latter does not seem to be essential; it is sufficient that the atoms are capable of being set in motion by absorbing energy from the X-ray beam—the interaction of the primary X-ray beam with the oscillating atoms then produces the effect. The character of the possible atomic movements is classified into two essentially different parts falling in the infra-red and the elastic ranges of frequency respectively. Raman imagines the elastic low-frequency vibrations of the crystal lattice to arise from the displacement of the lattice cell as a whole from its equilibrium position. Interaction between these vibrations and the X-ray beam gives a background of diffuse scattering of low intensity proportional to the number of lattice cells irradiated. The scattered energy is spread over a wide range of angles so that the elastic waves, it is stated, cannot produce a sharp reflexion.

To the infra-red modes of vibration is ascribed the principal role in producing the observed reflexions, with intensities proportional to the square of the number of lattice cells. These modes of vibration are supposed to arise from the movements of the atoms within the cells of the lattice. There is a difficulty here: the classification of the vibrations will hold for molecular crystals such as benzil, say. In these we might suppose the (infra-red) vibrations of atoms within one molecule to be controlled by forces different from those which control the vibration of the molecules as a whole (elastic waves). But in metal crystals we can choose a cell containing but one atom, and there is no distinction to be drawn between the vibrations of the atoms as a whole and those of the lattice. The metals aluminium, sodium and lead all show, however, pronounced diffuse reflexions, although the elastic waves are not supposed to be capable of producing such an effect. Moreover, Raman explicitly assumes, as a limiting case it is true, that the infra-red vibrations have identically the same frequency, amplitude and phase in all the lattice cells of the crystal: in order that the centre of gravity of the cell may remain fixed, some atoms must move in opposite directions to others, an idea that leads to difficulties as the number of atoms in the cell diminishes.

When the assumption just mentioned as to the identity of phase of the infra-red vibrations in all lattice cells is abandoned, it is assumed that the phase varies slowly from place to place in the crystal. We are then presented with the difficulty that the variation of phase is propagated through the crystal, a process which must involve the elastic properties of the lattice; yet these are supposed to be without effect in producing the most salient features of the X-ray pattern.

It seems unlikely that the quantum hypothesis as set out by Raman can be reconciled with the elastic wave explanation unless one or other hypothesis is radically altered. Although Sir C. V. Raman is confident that his quantum mechanism is essential, it must be admitted that the "thermal-elastic" theory does give a reasonably accurate account of the observed facts.

OBITUARIES

Prof. L. J. Henderson

BY the death of Lawrence Joseph Henderson, the U.S. National Academy has lost its foreign secretary, Harvard University a notable personality, and the United States an outstanding man of science.

Henderson was born in 1878. He graduated at Harvard in arts and medicine. A couple of years were spent in Strassburg, principally in Hoffmeister's laboratory, but he spent some time acquiring technique in organic chemistry in Thiele's institute, and his mind at that time was in close contact with that of Faust and the work of Schmiedeberg's laboratory. On returning to Harvard, Henderson was made lecturer in biological chemistry; in 1910 he became assistant professor, and in 1919 professor.

A remarkable range of knowledge enabled Henderson to contribute in ways not open to those whose intellectual background is more restricted. Versed in the disciplines of mathematics, science, and philosophy, he could place a physiological problem either in a more mathematical or a more philosophical frame than could most of his contemporary biologists. On the other hand, the manipulative aspect of experimental science made little appeal to him, and probably the particular satisfaction of 'bringing off' a difficult experiment was something which he was content to leave to others.

About the time when Henderson graduated, the buffering of fluids was one of the growing points both of physical and biological science, and Henderson's first notable work dealt with that subject (for example, "Das Gleichgewicht zwischen Basen und Säueren im tierschen Organismus", *Ergeb. der Physiol.*, 8, 254). The milestone which marks that phase is the "Henderson-Hasselbalch equation", stating that the hydrogen ion concentration of a solution containing carbonate, bicarbonate, and carbon dioxide is proportional to the ratio of the free to the combined carbonic acids. Perhaps his greatest contribution was his description of blood as a physico-chemical system. He described the red corpuscles in terms of the concentrations of eight components so connected that the alteration of any one equilibrium invoked a consequential alteration in all the others. This doctrine Henderson elaborated in his classical book "Blood"—the written record of his Silliman Lectures—in which, both for normal blood and that characteristic of certain diseases, the consequential inter-relations of the various factors involved were set forth in more than one hundred nomograms.

To such a mind as Henderson's, it was possible to treat of this great field without acquiring any mastery of the precise experimental techniques by which the data were obtained. It sufficed for him if the data which he plotted were reliable. He therefore, in collaboration with van Slyke, organized a large circle of extremely able experimenters, some in New York, some in Boston, and some farther afield, who undertook the necessary analyses.

It was not possible, however, for Henderson to treat of the physico-chemical blood picture, or rather blood kaleidoscope, without being intensely interested in the philosophical relation of environment to the change which it wrought in the blood of the organism. This interest was responsible for two books, "The Fitness of Environment", and "The Order of Nature". soThe study of environment at once locates Henderson's veneration for Claude Bernard, and the name of Claude Bernard leads to Henderson's love of France. He particularly enjoyed the tenure of exchange professorships at Paris and Grenoble. He held the Legion of Honour, and was a foreign member of the Académie de Médecine (Paris). He travelled on French ships, and enjoyed French wines and French cookery. Henderson was no mean cook himself; indeed, during the war years of 1917–18 he was a constituted American authority on the properties of gluten and the science of baking. Other books were "The Fitness of Environment, and "Pareto's Sociology".

Henderson was a wonderful friend and a wonderful host, particularly perhaps at his summer camp, at Morgan's Center in Vermont. He loved to entertain his friends, and so did his wife. Morgan's Center is in hilly country—country which had once been in cultivation, but now has relapsed to a birch wood. Here on the edge of the lake, the very edge (so that you can dive in from the verandah), was the central cottage where one ate and smoked; the premises expanded on what Henderson called the 'village system', which meant that he bought some window frames from a Chicago stores, and the local carpenter built a hut of perhaps a couple of sleeping rooms around the windows.

The nineteen-twenties were prosperous years in the United States, and the loyalty of her sons saw to it that Harvard participated in full measure. Under the wise guidance of President Lowell it was a time of great expansion on both the scholastic and social sides. In the planning of this expansion Henderson took a very important part—a part for which his wide academic outlook on one hand, and his great social gifts on the other, made him peculiarly valuable. Chairs were created, departments came into being on a basis of wide culture; among these must be mentioned the Fatigue Laboratory of the Harvard School of Business Administration, which dealt largely with muscular fatigue, in its widest sense, and the establishment of a human base-line in such matters; this was Henderson's peculiar *pied-de-terre*. On the social side the expansion took the direction of an endeavour to incorporate into Harvard what was socially desirable in the older English universities while in no wise doing violence to Harvard itself. While, therefore, Harvard still remained Harvard, new houses of residence sprang up, each presided over by a Master, and named after great Harvard men of former times. Thus there was a considerable increase in the number of men—as we would say—'in College'. But among the other new features of the Harvard constitution was one particularly precious to Henderson, one for which he was largely responsible, and one of which he was himself chairman, "The Society of Fellows"*.

This tribute would be incomplete without a reference to Henderson's intense desire to knit more closely British and American science, and probably he did much more than appears in successfully accomplishing this. Yet his work was a broader one; it was to knit British and American culture, indeed to knit Britain and America themselves, not perhaps formally, but none the less really. It is significant that only illness prevented his giving the Pilgrim Lecture in London.

Lawrence Henderson received many foreign recognitions of his work, including an honorary Sc.D. in Cambridge. He married Edith Lawrence Thayer in 1910 and leaves one son.

A few weeks ago Sir Charles Sherrington passed a photograph of Lawrence Henderson hanging in the Laboratory. He glanced at it and said, half to himself, "A great man, that."

J. Barcroft.

---

* The term 'fellow' is used in at least three senses at Harvard. (1) The charter of 1650 vested "sundry guiftes legacies landes and Revennewes in the President and Fellows". Now, the Corporation consists of the President, five fellows and a treasurer, who in the last resort act subject to the Board of Overseers elected by the graduates. (2) The Society of Fellows, consisting of nine senior fellows, of whom the President of the University and the Deans of the Faculties of Arts and Sciences are *ex-officio*, while the chairman (lately Lawrence Henderson) and six fellows are elected by the Corporation and confirmed by the Board of Overseers. The senior fellows select junior fellows and recommend them to the Corporation for appointment. "These men are selected for their promise of notable contribution to knowledge and thought. . . ." A junior fellow has free board-residence in a house and an annual emolument of 1,250–1,500 dollars. (3) Numerous fellowships also exist in connexion with the faculties which are of the nature of senior studentships.

Prof. Walter Nernst, For. Mem. R.S.

IN the passing of Walter Nernst, Nobel laureate, physical chemistry has lost a notable leader. From 1894 he was professor at Göttingen, from 1905 in Berlin, afterwards, until 1924, director of the Reichsanstalt, and from 1925 until his retirement director of the Physical Institute in Berlin. After training as a physicist he became assistant in Ostwald's laboratory in Leipzig, where he was additional professor in 1891, and his earlier work was concerned with the broadening and deepening of what was then the 'new' physical chemistry, which centred around the theory of electrolytic dissociation and was so enthusiastically received and developed in the Leipzig school. Ostwald turned more and more from the atomic and molecular conceptions then ruling in chemistry, and sought to replace them by "Energetics", or non-hypothetical laws based on the transformations of energy. Nernst always insisted, on the contrary, that thermodynamics and molecular theory must hold equal rank in a complete interpretation of physico-chemical phenomena. This is the key to nearly all his work, and is reflected in the title of his text-book: "Theoretical Chemistry from the Standpoint of Avogadro's Rule and Thermodynamics".

Of the large number of subjects which Nernst investigated, it is only possible in a brief notice to mention some in which he appears as a theorist and experimenter of great originality. These include his work on electrochemistry, the heat theorem and the quantum theory of solids.

In the electrochemical researches, three groups are most prominent. The first was the theory of the galvanic cell based on the idea of electrolytic solution pressure—the tendency of an electrode to throw out charged ions to a limit balanced by the osmotic pressure of the solution, and so to develop a potential difference. The formulæ based on this are still the foundation of the theory of electromotive force. Incidentally, his proposal to use the hydrogen electrode as the standard of electrode potential is still in use. Closely related to this work is that on the potential differences set up between solutions of electrolytes in contact. The theory of the effect of an electrolyte on the solubility of another having a common ion ('solubility product') threw light on many branches of chemical work, and the so-called distribution law, giving the way in which a substance distributes itself between two non-miscible solvents, is one of the most important in the study of heterogeneous equilibrium.

In his treatment of thermodynamics, Nernst made use of Helmholtz's equation relating the diminutions of energy (U) and free energy (A) in a process with the temperature coefficient of the free energy (dA/dT), itself equal to minus the entropy increase ($-\Delta S$), namely, $A-U=T. dA/dT$. He used this equation with great ingenuity in various fields, and its form lent itself very well to the discovery of the famous Nernst Heat Theorem (sometimes, and by Nernst himself, called the Third Law of Thermodynamics). By an inductive process, based on an extensive knowledge of the experimental results—another characteristic of his procedure—he singled out a field of changes in which the equation $dA/dT=0$ approaches exact validity as the temperature approaches the absolute zero. This implies that $A=U$, and many years previously he had pointed out that this—the so-called Thomsen-Berthelot principle—had a kernel of truth, which could never be disclosed apart from the numerical data. The Nernst Heat Theorem was at first mostly used in the calculation of chemical equilibria from thermal results. In its later developments its intimate relation with the theory of entropy and statistics has been made clear.

It was characteristic of Nernst that he quickly appreciated new discoveries and theories, and that he usually recast the theory into a more intelligible and practical form which appealed directly to chemists. The quantum theory, which was strangely overlooked in England, he recognized as likely to transform many branches of physical chemistry, and in two directions, in photochemistry and the theory of solids, he turned it to most fruitful applications. In the experimental work on the heat capacities of solids at very low temperatures he showed great skill in devising new apparatus—including the use of a metal block as the calorimetric substance—and gave a firm foundation to the quantum theory of specific heats. He invariably strove towards simplification and elimination of redundancy both in theory and in apparatus, and in this work liquid hydrogen was made available in quantity by means of a very simple and effective apparatus at a time when it was regarded as a rarity in most laboratories. He was also interested in the technical applications of physical chemistry, and the Nernst lamp well illustrates his practical ingenuity.

Nernst's work lies at the foundation of many branches of physical chemistry which are most actively studied at the present time, and all physical chemists recognize his outstanding contributions to their science. J. R. P.

Rev. H. J. Riddelsdell

Harry Joseph Riddelsdell entered business after school, but studying in his spare time took the B.A. degree of London and gained an exhibition at Jesus College, Oxford, where he graduated in honours and won the Hall-Houghton Prize. He took Holy Orders, and after holding a curacy at Leeds parish church became sub-warden of St. Michael's College, Llandaff, a post he held for seventeen years. In 1914 he was appointed rector of Wigginton and later became vicar of Bloxham. He retired from parish work in 1936 and died on October 17, 1941.

Riddelsdell's long residence in the country gave opportunity of using his quick eye and active mind in observation of Nature, and enabled him to make a thorough study of the flora of the neighbourhood. In 1907 he published "A Flora of Glamorgan", and from 1901 he contributed numerous notes to the *Journal of Botany* and other periodicals. He was a frequent contributor to the Botanical Exchange Club and sent valuable notes for the annual reports. The difficult and critical brambles became a special subject under the guidance of the Rev. W. Moyle Rogers, and after the death of the latter Riddelsdell became the leading authority on the genus in Britain and determined specimens for collectors. He visited many parts of Great Britain for the purpose of this study and a number of new forms were described.

The work to which Riddelsdell gave most of his leisure and ripe knowledge was the flora of Gloucestershire, sponsored by the Cotteswold Naturalists' Field Club. From 1908 as editor he organized and directed the work of Club members and dealt with the large quantity of lists and records already accumulated. A final revision had begun when illness compelled him to leave the task unfinished.

Riddelsdell was first and foremost a faithful and scholarly servant of the Church, devout and unselfish and loved by all around him. In addition, his energy, enthusiasm and quick apprehension enabled him to accomplish much in his leisure and made him a delightful companion in the field. He was elected associate of the Linnean Society in 1925 and his valuable herbarium is preserved in the British Museum (Natural History). W. C. Barton.

We regret to announce the death of Captain Guy Dollman, assistant keeper of zoology (first class) in the British Museum (Natural History), on March 13, aged sixty-five.

NEWS and VIEWS

New President of the American Association

Prof. Arthur H. Compton, Charles H. Swift Distinguished Service professor of physics in the University of Chicago, was elected president of the American Association for the Advancement of Science by the council at its meeting held on December 31. Prof. Compton is well-known for organizing and carrying out world-wide investigations of the reception and properties of cosmic rays, and for the influence he has had on education. He is a member of a family that has become famous in one generation, his brother, Dr. Karl T. Compton, president of the Massachusetts Institute of Technology, having been president of the Association in 1935, and his brother, Dr. Wilson Compton, having been a member of the Finance Committee of the Association during 1933–41. Dr. Arthur Compton was born in Wooster, Ohio, forty-nine years ago. He graduated from Wooster College in 1913, took his Ph.D. degree at Princeton University in 1916, and he has received honorary degrees from several universities. He has been on the faculty of Wooster College, Princeton University, the University of Minnesota, Washington University, and finally in the department of physics of the University of Chicago since 1923. Dr. Compton was a research physicist of the Westinghouse Lamp Company during 1917–19, a national research fellow at the University of Cambridge during 1919–20 and has been special lecturer at several foreign universities.

Thousand Dollar Prize of the American Association

The nineteenth Thousand Dollar Prize of the American Association for the Advancement of Science was awarded at the recent meeting in Dallas to Drs. Dugald E. S. Brown and Douglas A. Marsland, of New York University, and Dr. Frank H. Johnson, of Princeton University, for two joint papers: (1) "The Reversible Denaturation of Enzymes as a Determining Factor in the Reaction of Biological Systems to Temperature and Pressure" and (2) "The Mechanism of Temperature and Hydrostatic Pressure Reversal of Narcosis in Luminous Bacteria". In these papers an interpretation for the reversible biological effects of pressure is presented, and the quantitative evidence seems to be fully conclusive and is directly referable to basic principles of thermodynamics. In solving the problem of pressure, evidence has been found for a new general understanding of temperature relations in biological processes. A new concept, also supported by clear-cut evidence, is introduced with regard to the mechanism of narcosis. Thus a common denominator appears to have been found for three fundamental factors in biological processes—pressure, temperature and narcosis—wherein diverse effects can now be related to the same fundamental mechanism, itself in accord with familiar laws of physical chemistry.

Dr. Brown was born in St. Thomas, Ontario, in 1901, and studied at the University of Michigan and received the Ph.D. degree from Cornell University. Dr. Marsland was born in Brooklyn in 1899 and received the B.S. and Ph.D. degrees from New York University and the M.S. degree from Columbia University. Dr. Johnson was born in Raleigh, N.C., in 1908 and received the A.B. and Ph.D. degrees from Princeton University and the A.M. degree from Duke University.

First Publication of the Geological Society

At the meeting of the Geological Society on February 25, Dr. Leonard Hawkes reported the discovery in the Library of the Sedgwick Museum, Cambridge, of the first publication issued by the Society, a pamphlet of 20 pages, entitled "Geological Inquiries". The "Inquiries" were drawn up by a Committee in February 1808, three months after the foundation of the Society, and circulated among the members. At the time when Woodward's "History of the Geological Society of London" was published (1907), it was thought that no copies had been preserved. The pamphlet opens with an "Introduction" dealing with the scope and purpose of geology and with plans for the development of the science. In this we read that "Geology relates to the knowledge of the system of our earth, of the arrangements of its solid, fluid, and aeriform parts, their mutual agencies, and the laws of their changes".

The inquiries, of which there are 130, were collected from various sources "with a view to facilitate and in some measure to direct general research" in the hope "that by the labours and talents of many individuals thus united and assisted, several important objects may easily be attained"; and "above all, a fund of practical information obtained applicable to purposes of public improvement and utility". The following are examples of the inquiries: "Concerning Vallies [*sic*]. Do the opposite sides consist of the same kind of rock, and do they correspond in the inclination of their beds or strata ?" "Concerning Organic Remains. Do particular shells, etc., affect particular strata ? Are the shells worn, broken, crushed, or thrown out of their natural position ? Are the different species confusedly intermixed ? Among the various organic remains, can any traces be observed of the existence of man ?"

Raw Materials in the New World Community

The collective organization of all human beings into some form of world community, with a planned co-ordination of human activities of all sorts, was predicted as a result of the War by Prof. Kirtley F. Mather, professor of geology in Harvard University, at the Cranbrook Institute of Science on January 30. He considers that, regardless of the outcome of the War, the old order will inevitably be replaced by a new order that is even now being formed. This organization of individuals into a world society is the inevitable consequence of the extensive use of natural resources that are unevenly distributed over the face of the earth. The ceaseless flow of things from mine and quarry, field and forest, to processing plants, mills and refineries and thence to consumers is a fundamental necessity in an age of science and technology. It is quite likely that the historian of the future will rate this middle third of the twentieth century as equal in significance to the closing third of the fifteenth century. To-day, just as in that ancient time, human civilization is moving from an era that is closing into a new era that is opening.

There is actually an abundance of the needed raw materials, Dr. Mather said. A careful appraisal of the world stores of non-renewable resources, including known substitutes for such resources as petroleum that are known to be present in insufficient amounts, reveals the fact that there is enough and to spare of all the necessary raw materials to provide the physical basis for the efficient, comfortable existence of every human being who is likely to be born anywhere on the earth during the next two thousand years at least. Science and technology are even now inaugurating a new relationship between man and the things he needs or thinks he needs. For a century or more the tendency has been to use more and more of the non-renewable resources, Nature's stored capital, and relatively less of the renewable resources, man's annual income. For example, between 1900 and 1925 we used up more of the world's resources of the various metals and mineral fuels than had been used by man throughout his entire history prior to the year 1900. But within the last decade, scientific research has reversed the trend. The expanding chemical industries with their plastics and synthetic resins depend largely upon living things, and these are a product of the potentially inexhaustible resources of the soil. Long before the capital stored by Nature throughout geological time has been exhausted, man may well have learned how to live within his annual income.

History of Anglo-Czechoslovak Relations

UNDER the Czech title, "Sedm Set Let angločeských Vztahú", Dr. Kamil Kleiner has written for the benefit of Czechoslovak readers outside Nazi domination an account of the links between his nation and Britain. The earliest connexions were mainly exchanges between the theologians and educationists of the Universities of Oxford and Prague. With the development of the Bohemian University, founded by Charles IV in 1348, other learned men were attracted to Prague. Among them were Dr. John Dee, mathematician to Queen Elizabeth, and Edward Kelley, who visited Rudolf II in 1584 and stayed some years in Bohemia, which was then an important centre for alchemy and astrology. Dee eventually returned to England, but Kelley remained and after a chequered career died, according to Dr. Kleiner, in prison at Most in 1591.

After the time of Comenius's visit to England, 1641–42, there were few non-political contacts between Czechoslovakia and Britain until the nineteenth century, when English works were widely translated into Czech as a consequence of the national movement which began about 1790 with a revival of interest in the natural sciences and gained momentum in the early part of last century. The restoration of the Czech University in 1882 (it had been Germanized after 1620 when the Czechs lost their independence at the beginning of the Thirty Years' War) gave a further impetus to cultural relations with men of science and learning outside Bohemia. Czech students came to England, and British students and others, men of science among them, studied in Czechoslovakia, especially during the twenty years of independence. The disastrous developments of the last few years may still serve to strengthen the ties between Britain and Czechoslovakia.

Future of the Railway Oil Engine

ACCORDING to B. Reed, in a paper read before the North-East Coast Institution of Engineers and Shipbuilders, the most important factor influencing the whole future of any transport engine will be the fuel available. It will be absolutely necessary that the type of oil engine now used in road and rail transport shall be able to burn successfully fuels inferior to the present light Diesel oils. All development and applications will be governed very largely by this one factor, and the solution of the problem cannot be tackled too early. The spread of the War is increasing the difficulty of access to crude oil producing areas, and there is a question of whether the supply of fuels with a high cetane number will give out before the majority of high-speed engines have been adapted to burn successfully the lower grades of oil. Considerable technical progress has been made already in the burning of tar oils and vegetable oils, but the majority of engines are suitable only for the light Diesel fuels. The large slow-running locomotive type of engine certainly can burn heavy crude fuels without a great amount of trouble, but the far more numerous smaller high-speed engines for rail-cars and train sets need concentrated study, because it is essential they should be able to burn the poorer and heavier fuels without diminution in top rotational speed. The time available for ignition and combustion is one of the factors deciding the suitability or practicability of a fuel. Any standard engine of the future ought to be suitable for burning two or three different kinds of fuel, say, two heavy minerals and a vegetable oil, with the least possible modification.

Influx of Rare Winter Birds into Britain

THE recent severe winter, like that of 1939–40, has brought a considerable number of uncommon winter birds to various parts of the British Isles. In *The Times* of February 10, *et seq.*, Dr. D. A. Bannerman and others have reported most unusual numbers of rare waterfowl on the Thames at London, including pintail, gadwall, goosanders and hundreds of tufted duck, pochard, mallard and several shoveler, teal, shelduck, cormorants, coot, glaucous gull, great crested grebes, etc. The No. 2 (March) war-time number of *Country-Side* records the Iceland gull at Hammersmith; firecrests in Middlesex; eider and brent goose in Cheshire; barnacle geese, Bewick's swans, hen-harrier and hooded crows in Lancashire; siskins in Cumberland; smew, golden-eye and black-necked grebe at Tring (Herts); a flock of nineteen waxwings in Norfolk feeding on privet; great grey shrike and goosander in Surrey.

Later this winter the Merseyside Naturalists' Association has reported in Cheshire smews, goosanders and the red-necked grebe; smews, bittern, golden-eye and velvet scoter have been at the Ellesmere lakes, Shropshire, while an invasion of waxwings has included many flocks in the eastern half of the country, especially in Yorkshire (*Naturalist*, February), but they have extended their invasion to Dorset (*Country-Side*, March). In Wales there have been black redstarts on the Orme's Head and a flock of fifty siskins in alders in Glamorganshire. Earlier in the winter a flock of 5,000 widgeon was counted in the Ribble Estuary (Hardy, "Birds of the Liverpool Area", p. 167), but a grey lag goose that appeared at Regent's Park was believed to be a tame visitor from Kensington Gardens. Immense flights of knots have been off many river estuaries; flights of grey geese have been unusually numerous over many inland towns. The bulk of the winter visitors, especially the duck, came from Christmas onwards.

Birds of the Midlands

THE Ornithological Section of the Leicester Literary and Philosophical Society has issued a twelve-page county report and status of birds for

1941, as indicated when it was founded last summer, and as well as Leicestershire and Rutland, the report covers Nottinghamshire and Northamptonshire records of importance; 129 species are mentioned in the list, and some interesting visitors were recorded. The unusual influx of uncommon birds during the hard winter, noted from other parts of the country, is also borne out by the January and February 1942 bulletins, which report considerable numbers of gulls and sewage farm visitors. Altogether, the Society's record book has evidence of some two hundred species noted this century.

Principal Timbers of Jamaica

It is known that until within the last few years there was no forestry department in Jamaica and little information was available on the subject of the remaining forests. Some data have been collected on the chief native timbers and these are published by the Department of Science and Agriculture, Jamaica, in Bulletin No. 29 (New Series), "The Principle Timbers of Jamaica", by Mr. C. Swabey, conservator of forests (Kingston: Government Printers, 1941). Jamaica has a forest history common to many other Colonies of the British Empire. When Columbus first sighted the island it was covered in dense forests. Of these but little remains to-day; the fine mahogany, satin wood, sandal wood, lignum vitæ and other cabinet and dye woods which found their way to the markets of Europe are things of the past, the exports to-day being negligible. The chief reasons are shifting cultivation, failure to replant, felling of young and immature timber, barking of economically valuable trees and wasteful conversion.

The Forestry Department of Jamaica will have a heavy uphill task to face. Meanwhile a wise step has been taken in the issue of this small pamphlet. As the author remarks, it is unavoidably incomplete, but with the collection of further data a re-issue will become possible. In any event some of the chief forest types are here enumerated. A great obstacle to identification, met by no means for the first time in the British Empire, is the correlation of native names. "Not only are different names applied to the same tree in different districts, but the same name is applied to whole groups of trees and to entirely different trees in different districts." This is apparently particularly evident in the sweetwoods (Lauraceæ), the bulletwoods (Sapotaceæ) and the redwoods (Myrtaceæ). A considerable amount of botanical research will be necessary in some cases even to confirm some of the scientific names of certain trees.

Leaf-beetles Collected by Darwin

In the issue of the *Annals and Magazine of Natural History* of February, Mr. G. E. Bryant of the Imperial Institute of Entomology describes some Chrysomelidæ, or leaf-beetles, collected more than one hundred years ago by Charles Darwin. It appears that the specimens were found while rearranging and incorporating accessions to the collections of the family just named in the British Museum. Those obtained by Darwin were collected by him on the voyage of the *Beagle* during 1832–1836. They are very small, obscure insects belonging to the Halticinæ, or flea-beetle group, and were from South America and the Cape of Good Hope. They came to the British Museum through G. R. Waterhouse and by purchase at the sale of the collection of the Entomological Society of London in 1850. It may be mentioned that the British Museum received some 2,500 specimens from G. R. Waterhouse.

Vaccination in Napoleonic France

In a recent paper (*Bull. Hist. Med.*, 10, 635; 1941) Dr. Robert C. Dunbar remarks that the introduction into France of one of the most important scientific discoveries of modern times was delayed by war between France and Great Britain, and by the difficulties of preserving cow-pox virus. War, however, was much less totalitarian at the beginning of the nineteenth century than it is to-day, as is shown by the fact that Jenner, with the consent of an enemy Government, could enter enemy territory to introduce a new medical practice. The medical men of Geneva, especially Prof. Marie Auguste Pictet and Dr. Louis Odier, played a prominent part in the introduction of vaccination into France. The French medical profession in the Napoleonic era, though ready to receive new ideas, was at the same time very cautious, and refused to accept Jenner's discovery until its value had been confirmed by numerous tests in various parts of France, particularly Paris, Lyons, Rheims, Bordeaux and Metz. The new discovery was favourably regarded by the personnel of the Consulate and most of all by Talleyrand, while Napoleon himself had a high esteem for Jenner.

Epidemics in Haiti

According to Dr. Rulx Léon (*Bol. Of. San. Panamericana*, 21, 31; 1942), ex-Secretary of State in charge of the Public Health and Social Assistance Service, several severe epidemics of smallpox occurred in Haiti in early times, including those in 1518, 1738, 1740 and 1741. In 1518 treatment chiefly consisted in the patients bathing in a river. In 1825 when another outbreak occurred, the soldiers were vaccinated. It was not until 1920 that the people began to take vaccination and isolation seriously as means of controlling the disease. The first case of yellow fever, imported from Martinique, was reported in Haiti in 1691. Epidemics occurred afterwards in 1733, 1735, 1739, 1743, 1745 and 1746, and were followed by very severe outbreaks in 1798, 1802, 1803 and 1804. No further epidemics of yellow fever occurred in Haiti, but a few sporadic cases were reported from time to time, confined to the white colony. Epidemics of malaria and typhoid were also reported in Haiti in 1739, 1742, 1744 and 1766. The endemic diseases which often proved fatal in Haiti were mumps in 1740, measles in 1741 and 1889, rabies in dogs and humans in 1762, 1768 and 1782. An epidemic of influenza with pulmonary complications also occurred in 1852. Three years ago, Port-au-Prince had its second epidemic of diphtheria since 1892, and in 1935 anthrax made its first serious appearance since 1775.

Meteorology in Burma

The Government of Burma's official "Report on the Administration of the Meteorological Department, Burma, 1937–41" is the first—and until the situation in the Far East becomes very different will also be the last—report of a meteorological service that was formed as a consequence of the separation of Burma from India. In November 1936 the Government of Burma decided to set up this Service with the aid of Dr. C. W. B. Normand, director-general of observatories, India. Burma was already in possession of some observatories that had formed part of the India Meteorological Service, and according to the scheme worked out by Dr. Normand, these were to be maintained to form the backbone of the new service, while the former forecasting office at Rangoon, which was closed down as a measure of economy in 1932, would be reopened to form its headquarters. It was also arranged that at first the Meteorological Office at Calcutta would retain responsibility for the issue of storm warnings to ports on the coast of Burma. The Government of India gave further important help for the scheme by agreeing to the appointment for five years of Dr. S. C. Roy, one of the senior meteorologists of the India Meteorological Department, as the first director of the Burma service, and of Mr. S. S. Lal and Mr. S. K. Das as assistant directors for the same period.

Administrative control of the observatories of Burma began on April 1, 1937, and by July 1, 1937, all meteorological work in Burma, except gale warnings for shipping and the supply of hydrogen to pilot-balloon stations, was in the hands of the new service, which in the short period of its existence made good progress in developing its organization. Arrangements were made for daily pilot balloon ascents at the two airports, at Akyab and Mingaladon, from the beginning of 1939, and during the four years under review six new second-class observatories were begun. A workshop and laboratory for the repair of instruments were set up. The Government of Burma agreed to the acceptance by the director of membership of the International Meteorological Organization. Of all this activity there is probably no trace left; if the service is revived after the War it will presumably have to begin again at the very beginning.

Earthquakes registered in New South Wales

ACCORDING to the seismological bulletin of the Riverview College Observatory, recently received, sixty-four earthquakes were registered at the Observatory during July–September, 1941. These were divided as follows: eighteen in July, twenty-one in August and twenty-five in September. On August 2 a strong earthquake commenced recording with iP_{EZ} at 11h. 47m. 09s. U.T. from an estimated epicentral distance of 28·9°. The first pulse was condensational, and the maximum amplitude attained on the Galitzin seismometer was 67·5 mm. (magnification 311), at 57m. 18s. U.T. The shock finished recording at 15h. 30m. U.T., having lasted nearly 3h. 43m. Some of this spread would be caused by the difference in speeds of the various types of waves from the focus. On September 4 a strong earthquake commenced recording impulsively on all three components at 10h. 27m. 38s. U.T. from a probable epicentral distance of 3,100 km. (= 27·9°). The epicentre of the earthquake was estimated provisionally to be at lat. 7° S., long. 155·5° E. which is near Bougainville in the Solomon Islands. It attained a maximum absolute ground amplitude at Riverview of nearly 0·09 mm. at 10h. 36m. 27s. U.T. and finished recording at 14h. 20m. U.T., having lasted approximately 3h. 52·5m. On September 12, 1941, an earthquake of considerable severity commenced recording impulsively on all three components (NS, EW and vertical) at 07h. 09m. 15s. U.T. from a rather doubtful epicentral distance of 37°. Maximum amplitudes of 56·1 mm. (E with $V = 305$) were attained on the Galitzin records at 07h. 26m. 32s. U.T. and the earthquake finished recording at 09h. 25m. U.T., having lasted some 2h. 15·75m. The recording is strongly suspected of having come from a multiple shock. These three recordings appear to have been the greatest during the three months. Some of the lesser recordings have been somewhat interrupted by microseisms, which makes their interpretation difficult.

International Seismological Summary

THE International Seismological Summary, for July–September, 1934 has just been received. It was prepared at Oxford by, and under the supervision of, Miss E. F. Bellamy and sent to the press on September 17, 1941. In all, 183 epicentres and initial times of earthquakes were calculated from data supplied by observatories throughout the world. Of these epicentres 127 were repetitions from old epicentres and 56 were new. It is well known that lines of weakness in the earth tend to persist so that repetitions of earthquakes are relatively common. Eight of the earthquakes listed (with most of the instrumental data concerning them) were exceptionally well recorded while 83 were poorly recorded, probably because they were weak shocks. Only two of the shocks are suspected of having a depth of focus other than normal (presumably about 15 km. deep). The small number of abnormal shocks is thus outstanding. Of the two shocks concerned, one was on July 22 at 19h. 57m. 0s. U.T. with a depth of focus 0·025 of the earth's radius below normal and an epicentre at lat. 36·5° N., long. 70·5° E. which is in the Hindu Kush mountains to the north-east of Kabul; the other occurred on August 30 at 16h. 25m. 57s. U.T., had the same depth of focus, and an epicentre at lat. 19·3° N., long. 145·7° E., which is to the north end of the Challenger Deep in the Pacific Ocean. Both these areas have been the scene of moderately deep focus earthquakes in the past so that the occurrence is not surprising.

Seismic Surveying in New England

FROM *Earthquake Notes* of December, 1941, the new editor of which is Mr. A. K. Ludy, we learn that at least two groups have been conducting seismic surveys in New England during the past few years. The majority of studies have been concerned with the depth of glacial deposits over the underlying bedrock in an attempt to discover something more of the preglacial history of the area in question. The Lowell, Mass., quadrangle was thus studied by Dr. F. W. Lee and others. The Weston Seismic Unit has made similar studies about the area of Boston in studying the bed of the preglacial Charles and Mystic Rivers. The most recent survey by this unit was an under-water survey in the bed of the present Mystic River near Everett, Mass. Under-water equipment was loaned to Weston College by the Humble Oil and Refining Co., of Houston, Texas. Seismic surveys of the Triassic rocks of the Connecticut River Valley were made during the summer of 1941 by the Weston College Unit near Springfield, Mass. The depth to the base of the Triassic formations as well as preglacial topography were measured in several places near the Massachusetts - Connecticut State line. This study was made in co-operation with the Geological Society of America.

Public Address Systems

In a paper with this title, read recently before the Institution of Electrical Engineers, Mr. S. Hill, of Standard Telephones and Cables, Ltd., first outlines the classification of public address systems and then proceeds to a brief mention of the early history of the art. The basic elements, that is, the microphone, amplifier and loud speaker are next reviewed, an illustrated description being given of the double-button, moving-coil and cardioid types of microphone; typical polar characteristics are shown in the case of the latter type of instrument. Mention is made of the interrelation between public address technique and the art of architectural acoustics, and it is suggested that the architect should have some basic knowledge of acoustics and the advantages and assistance given by a public address system, or that he should co-operate with acoustic experts. It is, for example, extremely difficult for the public address engineer to install a system in a completed building when he is confronted with artistic as well as technical problems, loud speakers with large exponential horns being very difficult to reconcile with a decorative scheme.

The paper then deals with the general aspects of the planning and installation of sound systems, paying special attention to the problems associated with time interval and reverberation in auditoriums. Reference is made to the disturbing effect of noise, its cause and mitigation. Auditory perspective is discussed and compared with controlled reverberation, mention being made of the remarkable effects which can be achieved by either of these means. A description follows of some typical public address installations, special reference being made to those used for the religious pageant, "Le Vray Mistère de la Passion", performed in Paris in 1936 and 1937 and for the coronation of King George VI and Queen Elizabeth in Westminster Abbey in 1937, and to the system installed in the Argentine Chamber of Deputies in 1939–1940. The paper concludes with a cursory review of present-day trends, and the author remarks that in the present state of the art it is not possible, except in a few simple cases, to determine a unique solution of each problem.

Electrical Space-heating Methods

Mr. R. Grierson, in a noteworthy paper recently published (*J. Inst. Elec. Eng.*, 89, Pt. 2, No. 7; 1942), dealt with space-heating by means of electrically warmed floors, as applied to surface-type air-raid shelters, from the points of view of the thermal electricity supply and economic problems associated with the subject. The heat storage method advocated employs 'soil heating' cable suitably buried or placed in ducts below the floor surface. The investigation is described in considerable detail, and it has led the author to the following conclusions. No other form of space-heating provides an even approachable standard of thermal comfort for all the shelter occupants in return for the cost of energy used and space occupied. The method provides thermal storage sufficient to maintain the warmth-comfort standard when the electricity supply is interrupted during peak periods or by bomb damage to cables, substations, etc. It provides maximum safety against burns and shock due to inadvertent contact with the source of heat energy.

The space occupied by the installation is very small, as is also the risk of wilful damage. Maintenance, apart from cable failure, is nil. The initial cost of the installation is reasonable, and the total cost of operation compares most favourably with that of other forms of space-heating installations. The thermal capacity of buildings having 14-in. brick walls and 6-in. concrete floor and roof is such that it is technically impossible to provide any acceptable standard of thermal comfort for all the occupants, in response to the turn of a switch. The space-heater described requires no iron or steel, and the total labour per kw. capacity installed is probably the lowest for any form of heater. In view of its inherent characteristic of thermal storage at or about room temperature, it would appear that there is considerable scope for post-war development for certain classes of building.

Electrical Equipment for Farms

The Federal Security Agency and the U.S. Office of Education have recently issued a useful booklet (Vocational Division Bulletin No. 209) entitled "Building Electrical Equipment for the Farm", which is well worth study by farmers in Great Britain. The numerous uses for electricity on the farm and the widespread increase in rural electrification in the United States during recent years have turned the attention of farmers there to the building of electrical equipment. This publication is accordingly designed to provide teachers of vocational agriculture with reliable subject-matter organized in usable teaching form in order that they may be in a position to offer systematic instruction on building safe and simple electrical equipment for the farm. Its subject-matter has been supplied by the Rural Electrification Administration and other reliable sources, and it includes hints on farm wiring, maintenance and repair; analysis of operative training for the construction of special electrical devices or appliances peculiar to the farm; statements of certain interpretive science and related information in connexion with the various electrical applications; numerous line and half-tone illustrations; a list of the farm uses of electricity; a glossary of electrical terms; and finally, a list of references on electricity and the farm. Details are given for the construction of a poultry water heater, ultra-violet reflector for poultry, electric pig brooder, electric hotbed, electric stock-tank water heater, electric chick brooder and pen, exhaust fan room-cooling unit, and a combination electric room-cooling and garden-irrigating device. Advice is also given on the installation of a portable electric motor. Twelve important rules are given for the safe handling of electricity, and stress is placed on the inadvisability of amateur wiring, it being emphasized that this should be done by a competent wiring authority or electricity undertaking. This booklet should prove invaluable to progressive farmers working large tracts of land, where, because of the distances involved, contacts with skilled engineering labour are few.

Dry Cell Manufacture

In order to assist Indian manufacturers who have experienced difficulty in producing dry cells comparing favourably with those available in the Indian market, a systematic study of cell manufacture was undertaken in the laboratories of the Government Test House and the results are presented in Bulletin

No. 23 issued from the Office of the Director of Scientific and Industrial Research (Department of Commerce, Govt. of India). The report avoids highly academic discussions of the problems involved and concentrates chiefly on matters immediately concerned with the industrial aspects. Indian firms which had been importing most of the raw materials from Germany before the War (to the value of not less than ten lakhs of rupees a year) have now perforce to seek other foreign sources, and a survey of the indigenous materials was carried out with the view of replacing the foreign products used in cell manufacture. As a result of this, certain Indian manganese ores have been found capable of giving output results comparable with foreign ores of good quality.

The electrochemical theory of cells is briefly treated at the commencement of the Bulletin, which then proceeds to give an outline of cell manufacture. The materials and machines used receive a very comprehensive survey, as also do production methods and testing. The influence of various defects are examined in some detail, and a section is devoted to a consideration of the economic aspects of production. The Bulletin is mainly concerned with the bag type of cell, such of the packed type as are on the Indian market being of foreign origin.

Young Farmers' Club Booklets

THE latest addition to the excellent series of Young Farmers' Club Booklets is No. 9, "Garden and Farm Insects", by A. J. A. Woodcock. Others recently published are No. 2, "Bee Keeping", by R. Gamble, No. 6, "Grassland", by J. O. Thomas, and No. 8, "Goat Keeping". The price of each booklet is 6*d*. or they can be obtained from the National Federation of Young Farmers' Clubs, Oaklings, Canons Close, Radlett, Herts., post paid 9*d*. The booklets are most attractively set out, with first-class illustrations, and the subject-matter is presented in a form which is certain to stimulate interest. Technical terms are not avoided, but are introduced so naturally that they will be absorbed rather than consciously learnt. As introductions to the various subjects the booklets may be unhesitatingly recommended, and they will provide a sound background of information which will enable better use to be made of the more specialized leaflets issued by the Ministry of Agriculture.

Eugenics in India

THE first *Bulletin of the Indian Eugenics Society* (Calcutta, 1941) is an interesting paper of some twenty-four pages. The foreword describes the origin of the Indian Eugenics Society, the headquarters of which at present are in the Bose Research Institute. The aims and objects of eugenic researches in Bengal are described by Mr. S. S. Sarkar, the general secretary of the Society. A general introduction describing the hereditary disabilities occurring in Bengal, and including figures from various sources, is followed by a discussion of the possible methods of eugenic research. One fairly full pedigree from South Bengal is given, but a single pedigree of this nature cannot provide any conclusive information. Towards the end of the paper there is a list of hereditary anomalies, with what the author considers to be their modes of inheritance. The rules and regulations of the Indian Eugenics Society are given.

Population of Sweden

ACCORDING to preliminary figures (*Anglo-Swedish Rev.*, February) there was an increase last year in the number of inhabitants of practically all the towns in Sweden. The population of Stockholm increased by 10,462, bringing the total up to 605,575. In 1940 the number of inhabitants in the capital rose by 7,600 and in 1939 by about 13,600. The number of births in Stockholm is still increasing, being 3,061 at the end of 1941—the biggest for many years, as compared with 1,715 at the end of 1940. In 1939 the excess of births was about 1,500, in 1938 about 1,000, and in 1937 and 1936 only 56 and 45 respectively. For the years 1935 and 1934 there was even a deficit of births, namely, 361 and 491 respectively.

Merseyside Naturalists

AT the annual meeting of the Merseyside Naturalists' Association held in the Liverpool Royal Institution on February 8, Dr. J. C. P. Miller, of the University of Liverpool, was elected president; Mr. R. K. Perry, of Liverpool Museums, vice-president; Lieut. J. Bolton, chairman; Mr. Eric Hardy, secretary; and Mr. J. F. Stirling and Mr. G. K. Robinson, assistant secretaries. A new bird-ringing section was formed under the care of Mr. J. F. Stirling to extend migration studies. The Association's recently published "Handbook on the Birds of the Liverpool Area" (Buncle, Ltd., Arbroath), covering west Lancashire, west Cheshire and North Wales, has proved a success, despite the difficult times for scientific publications. Recording will be continued, and a future handbook on the fishes is contemplated.

Committee on Medical Schools

MR. E. BROWN, Minister of Health, in the House of Commons, on March 26, replying to Mr. Jewson on the question of the Government's post-war hospital policy in relation to teaching hospitals, said: "The Secretary of State for Scotland and I have decided to set up a committee, under the chairmanship of Mr. W. M. Goodenough, with the following terms of reference: 'Having regard to the statement made by the Minister of Health in the House of Commons on October 9, 1941, indicating the Government's post-war hospital policy, to inquire into the organization of Medical Schools, particularly in regard to facilities for clinical teaching and research, and to make recommendations.' The following have accepted invitations to serve on the committee: Prof. T. R. Elliott, Mr. A. M. H. Gray, Prof. J. Hendry, Prof. A. V. Hill, Sir Wilson Jameson, Prof. J. R. Learmonth, Sir Ernest Pooley, Sir John Stopford, and Miss Janet Vaughan."

Literature of Food Investigation

THE Index to the Literature of Food Investigation, issued by the Department of Scientific and Industrial Research, of which No. 2, Vol. 13, September 1941 has now appeared (London: H.M. Stationery Office. 4*s*. 6*d*.) is compiled by Agnes E. Glennie, assisted by Gwen Davies and Catherine Alexander. It is arranged in fifteen sections under such headings as meat, pig-flesh, poultry and game, fish, eggs, dairy produce, fats and oils, fruit and vegetables, grain products, crops and seeds, theory of canning, engineering, etc., each of which includes brief abstracts covering patent literature as well as periodicals. There is an author index, and the publication brings together references otherwise scattered through a wide range of abstract periodicals.

Linkage of Physico-Chemical Processes in Biological Systems

IN a previous communication[1] Prof. F. G. Donnan—to whose kindness I am much indebted—has developed further an idea arising out of work in this laboratory[2], concerning the cellular accumulation of potassium ions in association with an intracellular chemical reaction. In this process an external diffusible anion, after passing through the membrane into the cell, is converted into an indiffusible anion or anion complex (using the term 'indiffusible' with respect to the membrane). The case chosen by Prof. Donnan was the simplest, in order to illustrate the principles involved. An important biological limitation of this simplest system would be that equilibrium can occur in this case only with a pressure difference if the potassium is accumulated. On discussing this matter with Prof. Donnan, it seemed to us of interest to present the condition when this limitation disappears, and in terms of the symbols of his letter.

We need consider only the final equilibrium state, or :

$$\begin{array}{cc:cc} & Y^- & N^+ & \\ (I) & \Sigma A^- & \Sigma A^- & (II) \\ & K^+ & K^+ & \\ \multicolumn{4}{c}{M} \end{array}$$

in which (I) represents the interior of the cell, (II) the fluid environment, M the semipermeable membrane, K^+ the potassium ion, N^+ an indiffusible cation (which may be taken as sodium ion) and ΣA^- various diffusible anions, of which one type combines with an indiffusible neutral substance X within the cell to form the indiffusible anion complex Y^-. For simplicity, as before, in order to illustrate the ideas involved, the applicability of the laws of very dilute solution may be assumed, and also that the ions A^- and Y^- are univalent. We have then the following relations (where C denotes molar concentrations, and accented letters refer to II) :

$$C_K = \Sigma C_A + C_Y \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$C_K \Sigma C_A = C'_K \Sigma C'_A \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$C'_K + C'_N = \Sigma C'_A \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

from which :

$$2C_K = C_Y + \sqrt{C^2_Y + 4\,(C'_K)^2 + (C'_K C'_N)} \quad . \quad (4)$$

and

$$2\,\Sigma C_A = -C_Y + \sqrt{C^2_Y + 4\{(\Sigma C'_A)^2 - C'_N \Sigma C'_A\}} \quad (5)$$

whence $C_K > C'_K$ and $\Sigma C_A < \Sigma C'_A$, when C_Y and C'_N have real positive values. Equation (4) gives the quantitative expression for the accumulation of potassium ions in the cell against a gradient. Simple relations can be deduced for the special conditions when the hydrostatic pressures within and without are the same. Thus

$$\begin{aligned} P_{\mathrm{I}} - P_{\mathrm{II}} &= RT\,\{C_K + \Sigma C_A + C_Y - (C'_K + \Sigma C'_A + C'_N)\} \\ &= 2RT\,\{C_K - (C'_K + C'_N)\} \quad . \quad . \quad . \quad (6) \\ \text{or} \quad &= 2RT\,(\Sigma C_A + C_Y - \Sigma C'_A) \quad . \quad . \quad . \quad (7) \end{aligned}$$

whence, if $\mathrm{P_I} = \mathrm{P_{II}}$,

$$C_K = C'_K + C'_N \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8)$$

$$\text{and } \Sigma C_A = \Sigma C'_A - C_Y \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9)$$

These equations show that at equilibrium an *equality* of hydrostatic pressures could occur *together* with potassium 'accumulation' when *both* C'_N and C_Y, that is, the concentrations of the indiffusible cation without and the indiffusible anion within, have positive real values.

The membrane system so described is simpler than that existing between plasma and tissue cells, but indicates certain important relations which have been experimentally verified[2]. For C'_N we may read the sodium concentration of the plasma, and for Y^- a system similar to phosphate esters. The full membrane system for muscle has been treated elsewhere[2], as also the relations controlling the volume changes.

[2] Boyle, P. J., and Conway, E. J., *J. Physiol.*, **100**, 1 (1941).

The biological condition, referred to by Prof. Conway, means that he is considering the case of a cell where the semipermeable cell-membrane does not act like an *elastic envelope*, the distension of which, when the cell volume increases, produces an increase of hydrostatic pressure inside the cell, but like an *inelastic surface-layer*, the superficial area of which can vary with variation of the cell volume without affecting the internal hydrostatic pressure, the latter remaining sensibly equal to the hydrostatic pressure in the fluid environment. Prof. Conway has made this point quite clear in the investigation published in the *Journal of Physiology*, to which he refers. In this publication Prof. Conway has deduced a remarkable cell-volume relation, which he has experimentally verified in the much more complicated case of the muscle fibre - plasma equilibrium. I hope Prof. Conway will not consider it an intrusion if I indicate briefly how his reasoning can be easily applied to the simpler case considered in his communication (the symbolism and equations of which I shall use).

From the equations relating to electrical neutrality in (I) and (II), and the equation of membrane equilibrium, we have

$$C_K(C_K - C_Y) = C'_K(C'_K + C'_N).$$

Combining this result with Prof. Conway's equation $C_K = C'_K + C'_N$ (which results from the equality of hydrostatic pressures), we obtain at once

$$C_K = C'_K + C_Y.$$

Hence $C_Y = C'_N$. This means that the condition of equality of pressures *alone* gives the relation $C_K = C'_K + C'_N$, while this condition *plus* the three other conditions (electrical neutrality in both phases and the ionic membrane equilibrium) yields the relation $C_K = C'_K + C_Y$. Thus we cannot have equilibrium with *both* these two relations unless the (internal) C_Y equals the (external) C'_N. Now C_Y may be put equal to $[X]/V$, where V is the cell volume, and $[X]$ is the original mass of X in the cell (X denoting the neutral indiffusible substance inside the cell, from which Y^- is produced). From this it follows that C'_N *determines the cell volume*, when the experimental conditions are such that $[X]$ is sensibly constant.

In conclusion, I am much obliged to Prof. Conway for his elucidation of the biological condition, and wish to thank him for his very courteous reference to my humble effort.

Dispersion of Cellulose Strands in Cell Walls

In the cell wall of plant fibres the submicroscopic cellulose strands are orientated in parallel. With some bast fibres they are orientated parallel to the cell axis (fibre texture), and with wood fibres or cotton hairs they follow the thread of a screw (spiral texture). In other cell walls the optical anisotropy suggests a dispersion of the cellulose strands as, for example, in sieve tubes and latex vessels (tube texture) or a complete random orientation as in certain parenchyma cells (folium texture)[1]. Such membranes must be built of a submicroscopic 'reticular texture' in opposition to the 'parallel texture' of the first-mentioned type.

From his research on conifer tracheids, the Valonia cell wall and the parenchyma of the Avena coleoptile, Preston[2] concludes that there exists only one type of submicroscopic cell wall texture, namely, the 'spiral texture', from which the fibre texture can be derived by steepening the pitch of the spiral. Therefore he takes only parallel textures into consideration, and the possibility of reticular textures with dispersed and ramified cellulose strands is not discussed: ". . . a change in the *dispersion* of a single direction . . . may only be accepted when other possible causes have been ruled out"[3]. His argument is as follows: The cell walls investigated show oblique extinction under the polarizing microscope. The extinction angle is said to represent the pitch of parallelized cellulose strands forming a spiral texture. This conclusion does not hold good, because the statement of oblique extinction proves only an oblique direction of the anisotropy, but by no means that the cellulose strands are parallelized. They may just as well be dispersed symmetrically to the observed extinction direction, which would be the statistical result of variously inclined cellulose strands.

Whether there is dispersion or not can be determined by the X-ray method or—as the X-ray analysis of single cell walls of isolated cells is impossible at the time being—by the tedious way of measuring the refractive indexes of the cell wall quantitatively. If all wall substances except cellulose are removed, we must expect the indexes of crystallized cellulose parallel and perpendicular to the observed pitch of the spiral[4]. But if there is dispersion those indexes have to be found between the major and the minor index of crystallized cellulose[5].

Fortunately there is a third, much simpler, way to prove the existence of scattered cellulose strands in membranes where dispersion occurs. After staining cell walls with chlorozinc-iodine a remarkable dichroism is observed in the polarizing microscope: in membranes with parallel textures the light is almost completely absorbed if the direction of the submicroscopic cellulose strands is parallel to the vibration plane of the polarizer, whereas no absorption at all is observed if the direction of the strands lies perpendicular to the vibration plane[6]. Therefore, it is only permissible to attribute a submicroscopic parallel structure to a single cell wall, if it gives the iodine dichroism black-colourless when turning the stage of the polarizing microscope. If, however, the membrane examined shows a measurable light absorption in both its extinction positions, the existence of a dispersion of the submicroscopic cellulose strands is established. In this way it can be proved whether there is a reticular texture in the cell wall examined. The angle of dispersion can even be calculated, if the absorption in the two main directions of anisotropy is measured. It is found that

$$\frac{D_{/\!/}}{D_{\perp}} = \frac{1 - \cos \alpha}{\sin \alpha}$$

where $D_{/\!/}$ is the optical density of the stained cell wall parallel and $D_{\perp}$ perpendicular to the cell axis (in case of parallel extinction), and α the angle of dispersion. By this method it is shown that the cellulose strands in the cell wall of latex vessels of *Euphorbia splendens* include angles of inclination from 0° to about 60° with the direction perpendicular to the vessel axis. The conception of a submicroscopic reticular texture is, therefore, valid for the cell wall examined.

Ground and Polished Prehistoric Artefacts from Ceylon

Until recently it was the accepted view that Ceylon lacked prehistoric artefacts with signs of grinding or polishing. The Island does possess them, and an interesting collection of large specimens so treated was obtained in association with ground bone artefacts and the common pygmy implements. The large artefacts lay at the surface and down to a depth of 30 cm. in the caves 'Udupiyan galge, lat. 6° 45′ N., long. 80° 20′ E., and Batadomba lena, lat. 6° 40′ N., long. 80° 23′ E., the smaller ones persisting to a depth of about six feet. Dealing solely with the larger, thirty-four were celts and hammer stones fashioned from pebbles and bore drill holes, twelve were slabs of untrimmed stone, generally pitted on both surfaces, possibly 'anvils' employed in making burins, some were grindstones, mortars and pestles (Fig. 1). Several were stained with hæmatite. All were made from the less durable rocks such as amphibolite, granulite, gneiss, basic igneous rock and their combinations with biotite and garnet. They displayed heavy patination, while chert pygmies found alongside were only feebly patinated and quartz ones were almost unaffected; this speedier disintegration explains why the larger artefacts of Ceylon remained unknown[1] until 1940.

In many pebble artefacts the stone worker, after drilling a hole on one surface, had attempted to obtain another in the same place on the opposite side. The presence of several pits on this side suggests that he did not always succeed at the first attempt (Fig. 1; 1, 2). As the ends of these artefacts are battered, they are apparently celts with pits drilled for hafting or gripping.

The 34 celts (Fig. 1; 1, 2) ranged in length from 73 mm. to 127 mm., the grindstone (3) was 114 mm. long, the mortar (4) was 155 mm. by 140 mm., the 12 anvils were 230–80 mm. long and 165–200 mm. broad (5).

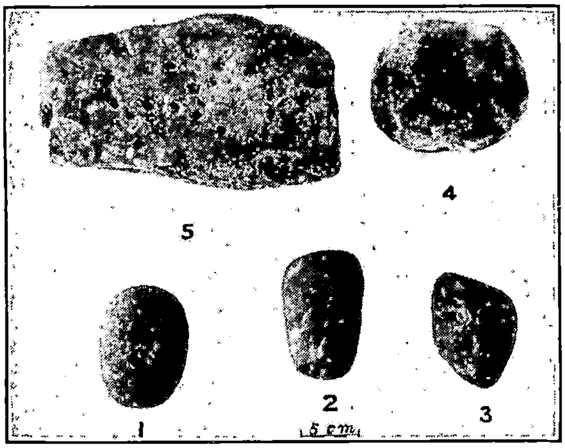

Fig. 1.
Large artefacts from Batadomba lena.

Bone artefacts comprising single points, rhombic forms with the narrower ends ground into conical points, and unmodified natural structures such as the toothed mandibular of the python (Fig. 2, *y*) and the spur-bearing tarso-metatarsal of the jungle fowl *Gallus lafayetti* Less. (Fig. 2, *z*) were apparently employed as piercing inplements.

In association with the artefacts were remains of animals of other existing species, such as swamp snails and bivalves, tree snails, crabs, mahsier, reptiles and mammals, as well as shells of the nut *Canarium zeylanicum* Bl.

The age of these artefacts needs consideration. There are two prehistoric culture phases in Ceylon[1]: (*a*) the *Ratnapura phase*, existing in association with fossils of hippopotamus and other extinct animals, and generally occurring at 12–40 ft. below the surface; (*b*) the *Balangoda phase*, occurring with remains of existing species and extending from the surface to a depth of about 6 ft.

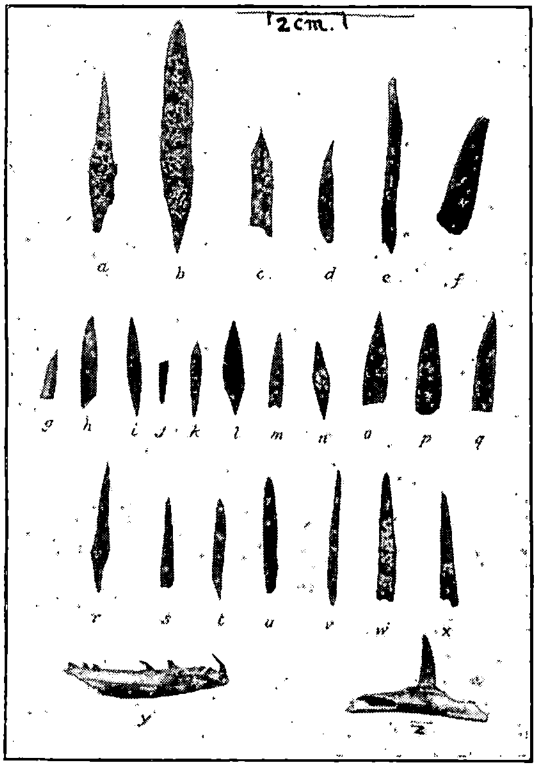

Fig. 2.
Bone artefacts from Batadomba lena.

The position of the larger artefacts here described, and the animal remains, suggest that they belong to the upper level of the Balangoda phase. The conical bottoms of the pits are characteristic of neolithic drilling, while the relatively fresh condition of some of the animal remains, and the survival of the Canarium nut shells, suggest that this culture phase survived until a comparatively recent date. The resemblance of the pitted pebbles to those from British lake deposits[2] and also to others from Bellary near Madras[3], when considered with the abundance of remains of swamp animals, is of interest. The artefacts cannot be ascribed to the so-called Väddhas, for these possess no tradition of the use of stone weapons, and further, regard the jungle fowl as taboo[4]. There is, however, the Väddha tradition of an extinct, hirsute, stone-using race of pygmies, the Äyo, who once competed with them[5].

The pygmy artefacts of Ceylon have been regarded by some as the work of a pygmy race, but the large size of the artefacts now discovered in association with such pygmy implements supports the view that their makers were not of abnormal size.

A detailed description will appear in *Spolia Zeylanica*, the journal of the Colombo Museum.

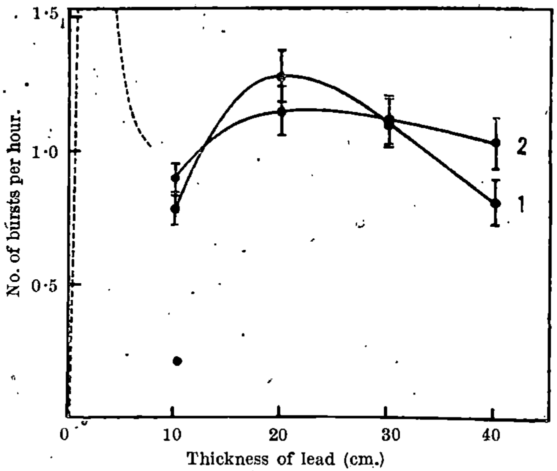
The Second Maximum in the Rossi Curve

It is well known that the rate of production of cosmic ray showers by layers of any material increases to a maximum as the thickness of the layer increases, and then falls off very slowly for much greater thicknesses, giving the familiar 'Rossi curve'. Certain observers[1] have investigated the rate of production of showers under large thicknesses of iron and lead with coincidence counters, and have claimed the existence of a second maximum in the curve, while more recently Swann and Ramsey[2] have found the effect with tin. Other observers[1], however, have not been able to confirm the presence of a second peak.

Using an ionization chamber to detect and measure cosmic ray bursts produced under large thicknesses of lead, we have obtained evidence for the existence of the second maximum in the Rossi curve, and found a possible explanation of the failure of some observers to find the maximum with coincidence counters.

Our apparatus consisted of a steel-walled ionization chamber of wall thickness 3 mm. enclosing two coaxial cylindrical wire grids of length 58 cm. and radius 11·1 cm. and 2·5 cm. respectively as electrodes, and containing air at a pressure of 8 atmospheres. The collecting electrode was connected to the grid of an electrometer valve set up in a balancing circuit, and changes in the plate current of the valve caused movement of the mirror of a Moll galvanometer of period 0·3 sec., this deflection being recorded photographically on a rotating drum. Bursts were recorded with thicknesses of 10, 20, 30 and 40 cm. of lead above the chamber, the sides of which were throughout surrounded with 10 cm. of lead to prevent showers from the walls and ceiling of the room from reaching the chamber. The chamber was placed with its axis of symmetry vertical, and calculations showed that the passage of about twelve ionizing rays through the chamber from a point above it would, on the average, produce a sudden displacement of 0·5 mm. in the trace on the film. We have reasons, however, for suspecting that many of the shower particles which originate in the lead above the chamber and strike the lead walls around the chamber—which is long in comparison with its radius—are scattered back into the chamber, possibly accompanied by secondary rays, with the result that a kick of 0·5 mm. may correspond to a burst of a very few rays, possibly as few as three or four. Our results, however, do not rest on this assumption.



The accompanying diagram shows the rate of production of bursts, corresponding to kicks of between 0·4 and 0·6 mm. (Curve 1), and that for kicks greater than 0·6 mm. (Curve 2). The limits of error indicated for each experimental value on the diagram refer to the standard deviation. The general form of the Rossi curve for thicknesses of lead less than 10 cm. is indicated for purposes of comparison (broken curve). It will be seen that the curve for the smallest bursts has a very pronounced maximum at about 20 cm., a value agreeing within the limits of experimental error with those obtained by the observers who have obtained a noticeable maximum with the use of counters. The curve for the larger bursts is, on the other hand, nearly flat.

This suggests that the failure of some observers to obtain the second maximum with counters is due to the fact that the probability of detection of a shower with most counting systems increases with the number of ionizing rays in the shower, so that with some arrangements of counters and for large thicknesses many of the observed coincidences would be due to many-particle showers. This would tend to result in a curve which was fairly flat like Curve 2. The suggestion seems to be supported by the results of Swann and Ramsey[2], who used an elaborate system comprising a large number of counters capable of recording only double coincidences, and who obtained with tin a definite broad maximum as marked as that of Curve 1. Schmeiser and Bothe[3] found that their curves for iron and lead showed a less pronounced second maximum when the lower two counters of their triple-coincidence system were farther apart. They therefore attributed their peak to small-angle 'hard showers', but the assumption of small angles between the shower particles seems unnecessary. We suggest that separating their lower two counters favoured the detection of the larger showers to a greater extent, so that the curve then obtained was more like Curve 2 than Curve 1.

We have obtained preliminary results for iron which already indicate that the same effects occur as with lead, though at greater thicknesses, as would be expected. Full details of this work will be published elsewhere in due course.

Geologists in War-time

I HAVE read with interest Prof. H. H. Read's account (NATURE, Jan. 10, p. 39) and the leading article in NATURE of March 14 on the lack of use of geologists in the present emergency, and can fully support the criticisms advanced. Included under the general designation 'geologist', however, are a number of other highly trained specialists the neglect of whom is not mentioned in these articles, but who are equally at a loss in their attempts to use their specialized knowledge to increase the war effort.

Every university department of geology includes on its staff, or on that of an associated department, petrologists and mineralogists, who must accept the decision that their first contribution is to continue the training of science students. Even where a reduction of staff leaves little time free from teaching duties during term, this pressure of work relaxes during the necessary vacations. The "fundamental dependence of industry upon mineral products", stressed by Prof. Read, does not end, however, when the raw material has been located, won and transported to the factory. In the chemical (including explosive) industry, the abrasive, refractory, ceramic and metallurgical industries, for example, process control and associated research must continue throughout manufacture and can most easily be achieved by the use of the chemical, optical and X-ray methods in which the petrographer, mineralogist and crystallographer are skilled.

Early in 1939 I played a small part in drawing up for the appropriate authority (on multipage documents each prepared in quadruplicate) a scheme for the utilization of the equipment, resources and staff of a particular laboratory; from that time three years ago the few problems which have reached that laboratory have done so through unofficial and accidental personal contacts. For the rest, the resources of the laboratory remain unutilized, the teaching staff chafe under a sense of complete frustration, while my carefully prepared quadruplicates doubtless languish untouched in some remote pigeon-hole.

MICROBIOLOGY OF THE ATMOSPHERE

ONE of the symposia held during the fiftieth anniversary celebrations of the University of Chicago last September dealt with the function of air currents, temperature and barometric pressure in disseminating insects, bacteria and such plant diseases as rust. Scientific workers participating in the programme on aerobiology of the American Association for the Advancement of Science, in co-operation with the Committee on Aerobiology of the National Research Council, took part.

According to investigations reported by Claude E. ZoBell, of the Scripps Institution of Oceanography, University of California, bacteria are less abundant in marine air, rain and snow than they are in air masses of continental origin. The ratio of bacteria over oceans as compared to those over land may be approximately 1 to 250. A particle the size of a bacterium would be carried nearly three thousand miles by a steady wind having a velocity of ten miles an hour before it would fall to earth from a height of 100 ft. Though many bacteria in the air are killed almost immediately by sunlight, desiccation and other adverse conditions, marine bacteria are known to survive suspended in the atmosphere for several hours. Terrestrial bacteria found over the ocean hundreds of miles from land necessarily must have been in the air for as long as a few weeks, Dr. ZoBell added.

J. J. Christensen, professor of plant pathology at the University of Minnesota, pointed out that plant spores, such as rust, produced in astronomical numbers, are carried over wide areas by the wind, making control of plant disease difficult. Corn smut, ne of the most prolific of plant parasites, can produce gall twenty to forty cubic inches in size on a corn plant in less than two weeks, and each cubic inch ontains about six thousand million spores. A single acre of corn with 10 per cent infection may produce 0 trillion spores. Spores have been found as high as three miles in the air, and high winds, gales, cyclones carry enormous numbers of these pathogens to considerable heights. Because they fall slowly—corn smut spore falls only one hundred feet in four and half hours—the spores can be carried thousands f miles by air currents to infect crops.

Spores of black stem rust do not survive the hot, ry summers of Tunis, but the crop is infected each ear, probably by spores blown across the Mediterranean from Sicily and Sardinia. Australian dust has been deposited in New Zealand. Spores of leaf nd stem rust of wheat are regularly introduced into Manitoba by the wind. Excessive rains and such arriers as mountains, large bodies of water and desert constitute real barriers to the passage of the pores and other micro-organisms.

Computations made for all seasons of the year as o the number of insects in a column of air one mile square, starting at 50 ft. above the earth's surface, and extending to 14,000 ft., indicate, according to erry A. Glick, of the Bureau of Entomology and Plant Quarantine, U.S. Department of Agriculture, an approximate average of 25 million insects. The density of the insects decreases with height. In the day-time, at 200 ft., there are about one half the number found at 20 ft.; at 1,000 ft. there are more han one third the number found at 200 ft.; at 000 ft. there are roughly half as many as are collected at 1,000 ft. At times, however, there are wide deviations from the average, as when the mayflies appear or termites are on their dispersal flights. Some species of insects are much more abundant at night than during the day.

Temperature probably has the greatest effect of any meteorological agent on the distribution of insects in the air. The most favourable temperature for insect activity ranges between 75° and 80° F., Dr. Glick said. Dew-point also is an important factor, the most favourable figure for insect activity being a dew-point of about 62°.

At times of approaching storms when the barometer is falling, Dr. Glick said that insects become nervously active. It has been found that the migrations of the sugar beet webworm in Russia is connected with cyclonic depressions. When the air is calm, the insects are not disturbed and relatively few are found in the air. Many insects will cling tenaciously to vegetation when the wind is too great for safe flight. More insects are collected at low altitudes when the surface wind velocity is about five to six miles an hour, but at altitudes from one thousand to two thousand feet a wind velocity of seven to eight miles is more conducive to large numbers.

Although the direction of winds is an important factor in the distribution of insects, such as the migration of the pink bollworm from Mexico to the United States, many insects fly across the wind, or against it. The height to which insects may go is related to their size, weight and buoyancy. Insects with large wing expanse relative to size and weight are found at great heights. Many wingless insects are wind-distributed. Spiders often are numerous in the air, being carried by their silken threads.

Not only the winds but also aeroplanes serve as important distributors for insects, Dr. Glick said. One investigator has found 191 kinds of live insects on aeroplanes arriving in the United States from Mexico and Central and South America.

Insects may be an important factor in allergy, for investigations have shown that insect particles in the air may be greater than all the pollen: butterfly and moth scales in particular may be an important cause of asthma in the United States.

A STUDY IN PLANT ONTOGENY

I. H. BURKILL has recently published (*J. Bot.*; August, 1941) a very stimulating morphological analysis of ontogeny in a pure line of *Ranunculus arvensis*. It is of interest to see the new light thus thrown upon general trends of development, and such studies would form a valuable basis for further developmental studies of an anatomical or physiological nature.

Mr. Burkill notes that the shoot apex, after bearing the two cotyledons, continues to develop primordia according to a regular 2/5 phyllotaxis system which is maintained in the floral axes. The primordia of vegetative and floral parts are initially all alike, distinguishable only during subsequent development, and it is concluded that the nature of their development is determined by the axis. The poorer the nutrition the fewer leaves precede the flower—6, including the cotyledons, in starved plants as against an average of 9 in the spring-sown crop.

The leaves show progressive dissection up the vegetative shoot and the concept is introduced of "foci of arrest", which make their effect felt progressively earlier, so that, while the first leaves are merely toothed, the later ones are deeply lobed and finally the lamina may be regarded as compound with each main segment carried by a petiolule. This analysis of leaf form succeeds in conveying a vivid and contrasting picture of the progressive complexity of the leaf as compared with the alternative view which stresses the greater laminar growth immediately around each diverging vein.

Leaf asymmetry is very constant in character, the up-spiral (anodic) side of the leaf showing evidence of earlier development of the foci of arrest. Some primordia show signs of transition from foliage leaf to sepal or from petal to stamen and in these two cases respectively the down-spiral (cathodic) side is more vegetative or petaloid.

After its gradual increase in size and complexity, leaf size falls off towards the flower, but size and degree of complexity do not run parallel, so that the first reduced leaves are smaller replicas of the complex vegetative leaves, suggesting that more than one trend is operative in leaf development. Leaf shape also shows a progressive change in general outline from obovate to ovate, this change persisting well up beyond the region of larger leaves.

The lower a branch arises on the axis, the more leaves it bears before flowering, so that on both main and lateral axes the same number of leaves tends to supervene between root and flower.

When the apex of the main axis produces a flower, this is followed in sequence by flower development upon the highest branch and so progressively down the plant, so that "flowering radiates from the upper pole of the plant". Branching, however, is stimulated by vegetative growth from below while the upper pole functions by checking growth (when apical growth passes into carpel development), whereupon the vegetative effort is directed into other buds.

The author has since communicated to the *Proceedings of the Linnean Society*, November, 1941, the results of a statistical study of meristic variation in the flowers of the same species. This has led him to suggestions as to the influences (possibly hormonic) at work in the production of cyclic whorls. Isomery is traced to the uniform dispersion of such influences, possibly along main lines of contact, the parastichies, while variations in length of plastochrone are then thought to separate the various whorls.

FITNESS FOR MILITARY SERVICE IN THE UNITED STATES

LEONARD G. ROWNTREE, chief of the U.S. Medical Division, Selective Service, explained the function of this Service and described some of the results at a meeting of the American Philosophical Society on November 21–22.

Selective Service is charged with the procurement of men for the U.S. Army; more than 17,000,000 men had been registered and more than 2,000,000 examined, at the time the paper was read.

The Selective Service and Army boards have rejected as unfit for military service approximately 50 per cent of the registrants examined. About 100,000 were rejected for illiteracy; 430,000 were totally unfit for military service, and 470,000 were classified as *I-B*; that is, they might be fit for limited military service were they acceptable under Army standards.

These figures are not to be interpreted as representing 50 per cent invalidism of the registrants examined, or as indicative of 50 per cent illness o the population in general. They simply represent unfitness for military service according to the standard requirements that have been set up by the Army.

These cases of rejections are as follows:

Cause.	No. of cases.	Percentage
Dental defects	188,000	20·9
Defective eyes	123,000	13·7
Cardiovascular-diseases	96,000	10·6
Musculo-skeletal defects	61,000	6·8
Venereal diseases	57,000	6·3
Mental and nervous diseases	57,000	6·3
Hernia	56,000	6·2
Defects of ears	41,000	4·6
Defects of feet	36,000	4·0
Defective lungs, including tuberculosis...	26,000	2·9
Miscellaneous	159,000	17·7
	900,000	100

Because of the relatively poor physical state of 5 per cent of the registrants examined and the urgen need for man-power for national defence, Presiden Roosevelt has suggested that as many as possible o those rejected be rehabilitated. It is estimated tha about 200,000 have remediable defects. This work of rehabilitation has been assigned to the Selectiv Service System. Plans have been formulated, an the work is already under way.

AUSTRALIAN WIND TUNNEL

THE Australian Council for Scientific and In dustrial Research has just completed th installation of a wind tunnel at the Laboratory o its Division of Aeronautics. The tunnel is of th closed jet, single return type, the working sectio being an irregular octagon 9 ft. wide by 7 ft. high.

The shell of the tunnel duct is constructed of $\frac{1}{4}$-in steel plate suitably stiffened, with the joints welded t preclude any tendency to leak, and ground flush t minimize surface roughness. The working section where the pressure is atmospheric, is made of woo to facilitate the erection of models. The cascades o turning vanes, placed at each corner to deflect th air, are also of welded steel, with adjustable trailin edge flaps. Sheet steel, wood and plastic rubbe were used to fair and fillet the cascades into the wall of the duct.

The 550-H.P. motor is mounted centrally in th return duct on seven radial supports, designed t remove rotation from the flow behind the six-blade 13-ft. diameter fan. Six of these radial straightene serve to lead cooling air into and out of the moto while the seventh carries the electric cables. A unusual feature is that the section of the duct carry ing the motor is separated from the rest of the tunne Air-tight joints are made between the flanges on eac side by inflated rubber tubes (actually cycle ty inner tubing).

The tunnel was designed both for research and f tests of aircraft designs, so that the design aimed the best compromise between high speed (that i large Reynolds number) and low turbulence. B avoiding expansion through the corner cascades, an reducing the expansion-rate in sections where chang of shape are occurring, a very efficient design has been achieved. This is indicated by the measured top speed of 300 ft. a second at 550 B.H.P., corresponding with an energy ratio of about 6·0. A honeycomb and settling length have been incorporated to ensure low turbulence.

Speed control of the motor is effected by the Ward-Leonard system, constancy of speed being aided by using a synchronous motor to drive the generator. Calibration tests show the velocity distribution to be within the desired tolerance of ±0·5 per cent of the mean, while there is a pleasing absence of organ notes, whistles or undue noise at any speed. Radiation from the steel shell prevents temperature rises of more than a few degrees during the normal time of a test run.

The balance is situated below the tunnel, and supports the model through three streamlined pylons which pass through the floor of the working section. It has been constructed to measure the lift, drag and pitching moment of the model, but provision is made to add linkages for measuring rolling moment, yawing moment and side force. The maximum forces for which the balance was designed are 1,000 lb. lift and 250 lb. drag. A high order of accuracy has been obtained by careful design and precise workmanship, and the accuracy obtained on calibration was about 1 part in 5,000.

A range of subsidiary equipment has been provided, including a 20 kw. frequency changer for driving small electric motors built into the aeroplane models to rotate the airscrews. Two such motors have been obtained from the United States; they are 3½-in. in diameter and 5 in. long and each develops 5 B.H.P. at 18,000 r.p.m.

The tunnel and balance were designed by the staff of the Council's Division of Aeronautics, and built in Melbourne by Messrs. Kelly & Lewis. The airscrew driving motor, and its Ward-Leonard control system, were supplied by the English Electric Company, and the fan was also made in England by the Airscrew Co.

GEOLOGY OF LIBYA

IN a lecture delivered before the Geological Society on February 25, K. S. Sandford[1] reviewed existing knowledge of the geology of Libya, his account being in the nature of a sequel to an earlier contribution[2] in which he dealt with the geology of northern Central Africa. The geology of Cyrenaica and Tripolitania is already fairly well known. The Fezzan and the central and southern deserts and oases have been visited by certain scientific missions the publications of which have only recently appeared.

The southern part of the region is dominated by three massifs, each of which extends into adjacent countries: 'Uweinat on the east, Tibesti on the south, and Ahaggar on the west. Each consists of Archæan and other Pre-Cambrian rocks flanked by Palæozoic sediments. Tertiary and later vulcanism has added to the interest of these massifs. Around 'Uweinat there are numerous plugs, craters and lavas; while the other two are crowned by great volcanoes, and rise to heights of about 10,000 ft. The three massifs are separated by sandstone plains which stretch far to the north, sloping very gently in that direction, the sandstones representing continental conditions which appear to have been widespread during later Palæozoic, Mesozoic and Cainozoic times from the French territory on the west, through central Libya, to southern Egypt and the northern Sudan. The sandstones of the plains in turn disappear beneath marine sediments, of Cretaceous and Tertiary age, which represent transgressions of the Tethys, the ancestral Mediterranean, from the neighbourhood of the Gulf of Sirte far to the south. Libya escaped the Tertiary mountain-building movements which formed the Atlas, but the Saharan platform was, nevertheless, warped, upheaved, and broken. The three massifs of the south probably owe much of their differential uplift to these movements. Late volcanic activity is not confined to these highlands, for in central Libya there are vast expanses of volcanic rocks of comparatively recent date.

The Palæozoic sediments, well seen on the flanks of Ahaggar, constitute a long record of marine transgressions from the west. Definitely Silurian beds follow sandstones of doubtful Lower Palæozoic age, and are succeeded by Devonian formations. A temporary retreat of the sea is marked by Carboniferous beds containing Lepidodendron. The final stages of the transgression are recorded by subsequent Carboniferous marine beds, the latest examples of which are interbedded with sandstones containing fossil wood. Marine Permian appears to be absent.

As the sea retreated during the Devonian and Carboniferous, the Palæozoic land of Egypt and the Sudan broadened westwards, and by Permian time Libya was probably elevated and subjected to denudation. Except near the coast of Tripolitania, the sea continued to be excluded from Libya during the Triassic and Jurassic periods. The first important marine transgression from the Tethys was during the Upper Cretaceous, when there may have been a north-and-south strait across northern Africa east of Ahaggar. The second great Tethys transgression carried a Lower Eocene sea southward from Sirte almost to the northern flanks of Tibesti. Middle and Upper Eocene marine beds were deposited over much the same area. In the neighbouring Egyptian marine area, where the Cretaceous is developed on a grand scale, the sea fell back considerably during the Middle and Upper Eocene, and through Oligocene and Miocene times the regression continued in Libya as well as Egypt. Miocene marine beds can be traced from the shores of the Gulf of Sirte through Cyrenaica into northern Egypt. Continental conditions, such as had prevailed since the late Palæozoic, with only occasional interruptions, over much of southern Libya, then extended over the whole territory.

MODERN SCIENCE AND MUSICAL THEORY

THE bearing of modern discoveries in acoustics on musical theory was discussed by Ll. S. Lloyd in a paper read before the Royal Society of Arts on March 4. While the tuning of musical instruments and mathematics have an association that goes back to Pythagoras, it was Helmholtz who first showed, just eighty years ago, that the scientific basis of musical theory must be found in the physiological and psychological sections of the theory of hearing. Modern acoustical research has completely vindicated, with ample experimental proof, a pronouncement which for Helmholtz was an expression of deep scientific insight. Pythagoras had put the question: "Why is consonance determined by the ratios of small whole numbers?" The tuning of strings formed the basis of the question. Overtones in a musical note had been detected by the human ear. Mersenne recorded four, as occurring at the octave, the twelfth, the fifteenth and the seventeenth of the prime. When it was discovered that a string could vibrate simultaneously, as a whole, two halves, three thirds, and so on, and that the periods of these vibrations fell into a harmonic series: $1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}$, and so on, corresponding to notes of the scale, the simple numerical relationships were regarded as explaining simple musical intervals. The insistence of Helmholtz that the basis of any scientific theory of music must be sought in the coöperation of ear and brain, aroused considerable opposition.

Helmholtz had made simple experiments with his siren to dispose of the idea that the energy or intensity of a vibration alone determines its loudness. If the energy of the vibrations was left constant, the tone of the siren was faint in the bass but painfully loud in the high treble. The work of Fletcher and Munson[1] has placed this result on a firm quantitative basis over a wide range of frequencies, so that it must now be recognized that loudness depends partly on intensity, partly on frequency, and partly on overtone structure.

The next idea to be given up is that pitch depends solely upon frequency. Fletcher[2] recorded the average judgments, by skilled observers, of the pitches of a series of pure tones produced over a wide range of frequencies with loudness-levels ranging from 40 phons to 100 phons. As a standard of comparison for fixing the pitch, he used a pure tone with a constant loudness-level of 40 phons. At about the middle range of frequencies the pitch may be flattened by a whole tone or more as the loudness is increased. At very high frequencies the pitch becomes sharper, not flatter, as the loudness is increased, but the changes are greatest at lower frequencies. When four harmonics were added to the pure tone, Fletcher obtained only about one fifth as much pitch-change. Pitch therefore is dependent partly on frequency, partly on intensity, and partly on overtone structure.

These facts add considerably to the complexity of interpretation of combinations of notes into chords. Furthermore, Fletcher has shown that if pure tones are sounded together, the pitch of the sound heard may be that of a pure tone below those generated. Musical chords are built not from pure tones but from notes each of which contains several harmonics. The simple numerical relationships got from dealing with pure tones are therefore inapplicable to combinations of musical notes.

Reference was made to the chromatic stroboscope designed by R. Young and manufactured in the United States by C. G. Conn, Ltd., Elkhart, Indiana. When the instrument was used to study the pitch relationships between the notes of well-tuned pianos, surprising divergencies from accuracy were observed. The ear is by no means so exacting about the intonation of the piano as some detailed discussions imply.

FORTHCOMING EVENTS

Wednesday, April 8—Friday, April 10

Science Masters' Association (at Rugby School, Rugby).—Forty-first Annual Meeting.

Wednesday, April 8

Evening—Mr. P. H. B. Lyon: "English in the Science Course" (Presidential Address).

Thursday, April 9

Morning—Prof. M. L. E. Oliphant, F.R.S.: "Recent Practical Applications of Nuclear Physics".

Afternoon—Mr. L. J. F. Brimble: "Human Biology in Education". Annual General Meeting.

Evening—Prof. L. Hogben, F.R.S.: "Science and Citizenship".

Friday, April 10

Morning—Discussion on "Science in Post-War Education", to be opened by Mr. E. G. Savage.

Thursday, April 9—Monday, April 13

British Psychological Society (at the Municipal Training College, Brighton). Extended General Meeting.

Wednesday, April 8

Society of Chemical Industry (Food Group) (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2.15 p.m.—Dr. J. Hammond, F.R.S.: "Animal Production in the Post-War World".

Thursday, April 9

Physical Society (Joint Meeting with the Science Masters' Association) (at Rugby School Science Laboratories, Barby Road, Rugby), at 10.15 a.m.—Mr. C. W. Hansel: "Fundamental Laws and Definitions in Physics", 1: Ohm's Law; 2: Specific Heat and Newton's Laws of Cooling; 3: Mass. Mr. P. Woodland: "The Need for a Permanent Standardization and Guidance Committee for Elementary Physics".

Friday, April 10

Royal Society of Arts (India and Burma Section) (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Diwan Bahadur S. E. Runganadhan: "The Work of Indian Universities".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Annual General Meeting.

Geologists' Association (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. F. J. North: "The Centenary of the Glacial Theory in Britain; Notes on Contemporary Manuscripts and Publications".

Institution of Mechanical Engineers (at Storey's Gate, London, S.W.1), at 5.30 p.m.—Mr. H. E. Dance: "Mechanical Aids to War-time Training".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Horticultural Assistant to the Agricultural and Horticultural Organizer—The Clerk to the County Council, Shire Hall, Bedford (endorsed 'Horticultural Assistant') (April 11).

Lecturer in the Department of Mathematics—The Registrar, University College, Singleton Park, Swansea (April 22).

Assistant Master to teach Mathematics and Elementary Science in the Junior Technical School—The Secretary for Education, Tudor House, Friar Street, Worcester (April 25).

Student-Demonstrator in Botany—The Principal, Royal Holloway College (University of London), Englefield Green, Surrey (May 1).

University Chair of Oil Engineering and Refining (Petroleum Technology)—The Secretary, The University, Edmund Street, Birmingham 3 (May 9).

University Chair of Radiology (Therapeutic) tenable at Middlesex Hospital Medical School—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (May 26).

Chief Metallurgical Chemist to take full charge of Steelworks Laboratories, for employment in the East—The Central Register, Ministry of Labour and National Service, Queen Anne's Chambers, Tothill Street, London, S.W.1 (quoting Z446X).

Assistant Metallurgical Chemist to act as Principal Assistant to the Chief Chemist of a modern Iron and Steel Works—The Central Register, Ministry of Labour and National Service, Queen Anne's Chambers, Tothill Street, S.W.1 (quoting Z447X).

CATALOGUES RECEIVED

Londex Synchronous Time Delay Relay, Type PRL, ranges 2 sec. to 28 days. (List No. 97.) Pp. 2. (London: Londex, Ltd.)

The Wild-Barfield Heat-Treatment Journal. Vol. 4, No. 30–31. Pp. 55–70. (Watford: Wild-Barfield Electric Furnaces, Ltd.)

ADULT EDUCATION AS A SOCIAL ACTIVITY

THE problems of man-power and woman-power to which attention has been directed by recent speeches of the Minister of Labour and National Service in view of the growing demands which the War is making upon our resources, have two main aspects, mobilization and utilization. The former is liable to receive more than its due share of attention, and the recent report of the Beveridge Committee on Skilled Men in the Services is a timely reminder that the reservoirs of labour, skilled or unskilled, male or female, are strictly limited. The mobilization of every available man or woman will be insufficient to develop our full fighting and productive powers unless there is wise apportionment of labour between the different fighting services, war production and the essential services, including civil defence, transport, and the like. Equally it will not be developed unless that disposition is made in conditions which call forth from each individual his or her maximum effort, and in which physical, mental and moral vigour can be sustained through whatever days of trial or endeavour lie ahead.

The question of morale is thus of supreme importance, and Mr. Bevin's remarks on management in his recent statement in the House of Commons may arouse misgivings as profound as any of the revelations in the Beveridge Committee's report. The responsibility of management in the maintenance of the conditions which promote industrial efficiency is so fundamental that the failure of the Minister to utilize the powers which he already possesses to deal drastically with inefficient management will recoil severely on his own head if not rectified. The co-operation between management or employer and the worker has two sides, but we cannot complain of lack of response on the part of the worker until the employer —and the Government—have done their utmost to establish the right conditions.

The prescience of Mr. Winant's words in his valedictory report to the International Labour Organisation last year has been attested by much that has happened in Great Britain and in the United States since they were written. The democracies cannot survive unless they achieve effective co-operation between Governments and organizations of employers and workers. Its absence is the primary and fundamental cause of waste of labour, whether in the neglect of personnel management, the failure to establish proper working conditions, to utilize the scientific knowledge acquired so painfully in the field of industrial health, or in the petty misunderstandings over income tax deductions and the like through indifference to psychology and the human element generally.

Mr. Bevin in his speech rightly referred to a great weakness in British industry due to the failure of employers to give the personnel management its proper status. Although over a very wide field of industry that mistake is now being rectified, we still suffer from the long neglect to extend the scientific study of the human side of industry. With adequate support in the past such bodies as the Industrial Health Research Board and the National Institute of Industrial Psychology could have been ready with a far wider range of experience for the solution of pressing problems. As it is, the reports of the Select Committee on National Expenditure, like the emergency reports of the Medical Research Council, bear melancholy witness to the failure to apply knowledge on hours of work and working conditions generally which were acquired a quarter of a century ago.

There are welcome signs that, in the Services as well as in industry, the scientific use of labour is being attempted on an increasing scale. The appointment of an advisory committee consisting of Dr. C. S. Myers, Prof. J. Drever, Prof. F. C. Bartlett and Prof. C. Burt to assist the Director of Personnel Selection shows that the Army recognizes the value of scientific knowledge in this connexion, and the annual report of the National Institute of Industrial Psychology affords other evidence of the utilization by the Services of scientific men in the training and selection of personnel. The scientific aspect, however, is only one side of the problem. Important as may be scientific selection and training of labour, the use of scientific knowledge to establish the best working conditions, to minimize hazards to health, to eliminate accidents and to reduce friction between management and workers, more is required if production is to reach its maximum efficiency.

Despite the emphasis placed on this subject by the Acting Director of the International Labour Office in his report to the International Labour Organisation Conference at New York last October, and the admirable report on War-time Developments in Government-Employer-Worker Collaboration prepared for consideration at the same Conference, neither in Great Britain nor in the United States can we be said to have reached the heart of the problem. Primarily it is one of education, and the main responsibility for initiative must inevitably lie on the Government. Moreover, it is a question of adult education; not merely of educating the adolescent entering industry for the first time, but rather of enabling the great mass of adult workers to understand what is required of them, to see their own part in relation to the task of the nation, and how their own zeal and efficiency and sacrifice can fortify the national effort and shorten the road to victory.

The vital importance of adult education in this matter has, generally, not been grasped. It completely transcends the scheme for joint consultative and advisory committees consisting of representatives of workers and managements already initiated for the Royal Ordnance Factories by the Director-General, Sir Charles McLaren. These committees are intended to smooth difficulties by arranging the regular exchange of views between management and workers on matters relating to improvement of production and increase of efficiency.

A constitution for Factory Production Committees was signed on February 26 by representatives of the Ministry of Supply and of all the trade unions having members in the Royal Ordnance factories. The functions of the committees are defined as "to consult and advise on matters relating to production and increased efficiency in order that maximum output may be obtained". Meetings will be held fortnightly or as required, but the workers' side is to meet weekly to expedite procedure. A central committee has been set up to ensure immediate and efficient application of the scheme and it will act as a pool for ideas.

This development is essentially an extension of the works council scheme which has been used by progressive firms for a number of years past. The important contribution it should undoubtedly make to efficiency and output should not lead us to overlook the fact that it scarcely touches the wider question of morale. One of the real weaknesses in morale in Great Britain is the lack of understanding and interchange of ideas between those who direct the War and those who are directed. Despite all the efforts of the Prime Minister himself and his great power of interpreting the situation and strategy of the War, this is notably true of industrial and civilian defence workers. Adult education is essentially related to morale in the waging by a democracy of total war.

While, however, the importance of education as a very corner-stone in reconstruction is widely appreciated, the importance of adult education in that respect, and still more in regard to the war effort, is almost completely overlooked or ignored. Adult education, it is true, receives passing mention in a pamphlet "Education for Democracy", by Barbara Drake, recently issued by the British Association for Labour Legislation (London: 1942. Pp. 44. 9*d*.); here the importance of developing systems of adult education as centres of social activity as well as seats of learning is recognized, as well as of encouraging voluntary bodies, organized on democratic lines, which provide suitable courses of adult education. The report referred to above on War-time Developments in Government-Employer-Worker Collaboration, however, does not even mention education.

The truth is that the War will be won and the peace made by the generation of men and women who are grown up now. Unless by adult education we attempt to correct mistakes in their outlook, training and vision, the growing generation may, like its predecessor, find its prospects once again shattered by failure of this grown generation to seize the opportunities opening now before it. Moreover, it should be remembered that the success of the war-time measures of co-operation between workers and employers and the Government is due primarily to the recognition of their validity and purposes both by the trade unions and by management. This recognition was largely due in turn to the need for expedition in settling grievances and to the special care taken to avoid arousing antagonisms by rigid enforcement. There must be some similar recognition and understanding by the mass of the people if they are to take their place in a new and better social order, and this it is a prime function of adult education to supply.

The contrast between the free nations and the totalitarian regimes is nowhere more marked than in this matter of the methods of democratic collaboration. The value of such collaboration in the formulation and application of a labour policy has been repeatedly demonstrated in dealing with the many problems involved in the allocation of man-power between industry and the Armed Forces, the control of employment, training and apprenticeship, dilution of skilled labour and transfer, and the mobilization of women and other labour reserves. As a recent P E P broadsheet on mobilizing woman-power indicates, it may well be a decisive factor in regard to the use of part-time labour. Tripartite collaboration, through its assistance in safeguarding the interests of workers in the factories, those mobilized for the army, and of seamen, both in the Mercantile Marine and in the Navy, has already made important contributions to the national morale, and has often made important contributions in such matters also as problems of safety, elimination of hazards, prevention of accidents from fatigue, overstrain and tension, and the promotion of industrial hygiene.

The full use of our national resources, whether in time of war or of peace, and the provision of the commodities and services necessary to raise or even maintain general standards of living, involve the full co-operation of employers and workers with the Government at every stage, from the initiation of a policy to its application and enforcement. The educational aspect of such collaboration is, however, often overlooked. National safety and efficiency make it essential, for example, that all groups in the community should understand the aims of certain measures—rationing restrictions, black-out precautions and fire prevention are typical examples. The part which organizations of employers and workers have played and must play in the interpretation of such measures and in carrying back into the local community understanding of the problems at issue and in furnishing explanations of policy is seldom appreciated.

Such educational work—education of the adult in a very practical sense—is one of the most important functions of the machinery of co-operation established during the War. Further, one of the most imperative needs at the present moment, if we are to attain and sustain our maximum productivity, is for a deliberate planned extension of adult education of this type. Without it the fresh sacrifices being demanded of us, the call to more spartan living and strenuous endeavour, may fail of their full effect and purpose through inadequate response, misunderstandings or avoidable friction. As already noted, the poor morale which at present exists in some sections of the people of Great Britain, particularly among industrial and in civil defence workers, is due largely to the lack of interchange of ideas and common principles of understanding between those who direct the War and those who are directed.

The maximum war-effort can only be obtained with the full co-operation of the consciousness of our society, and the lack of co-operative thinking, knowledge and discussion between the two sections of our democracy may be disastrous. We must have leaders who can explain to the members of the Services and the workers the longer-term geographical and historical implications of the War, the tasks before us, the dangers ahead, the principles and practical problems of the post-war era. Moreover, it is just as important that these leaders should listen to complaints as well as talk and interpret.

The recent debates in Parliament have shown how admirably the House of Commons is fulfilling the vital function of interpreting to the Government the mind of the nation. To meet the primary need, the suggestion recently advanced by Mr. Stephen Spender in *The Times* of February 25 of extending the idea of the education officer already found in the Army merits careful exploration. Mr. Spender suggests that there should also be education officers in factories, in civil defence and possibly in civilian life. Their task would be threefold: to assist the people to understand the tasks that face us as a people sharing common aims, principles and opportunities; to win conscious co-operation in the furthest aims of the War and the ensuing peace; and to equip the individual to be educated, socially responsible, and imbued with the principles of a less anarchic form of post-war society.

Whether or not some definite organization is required to implement this essential work of education, voluntary effort will still be required if only to fill the gap while some formal scheme is being elaborated. Without vision the people will indeed perish, and on all who have caught some glimpse of the values that are at stake, of science, of art, of religion, of any aspect of that tradition of humanism that has been handed down to us, or who have some understanding of the ultimate purposes for which we are fighting, lies the obligation to share it as widely as possible with their fellows. Scientific workers, many of whom recognized the challenge and threat to our heritage long before the outbreak of war, have a special as well as a general responsibility in this matter. With their responsibility for seeing that science makes its fullest contribution to the national effort, for waging relentless war on any source of technical or administrative inefficiency, lies this further responsibility of helping their fellow-workers, their comrades-in-arms and their fellow-citizens to share that vision of deep purpose and final victory, and, sharing it, to see the part which each must play in the furtherance of that purpose, the winning of that victory and the shaping of the nobler order in which that purpose will be achieved.

THE WAR-TIME SOCIAL SURVEY

A RECENT report of the Select Committee on National Expenditure provides a striking vindication of the War-time Social Survey of the Ministry of Information, which has been the subject of much adverse criticism. The appearance of the report is of special interest at the moment in view of the renewed attention being given to the organization of social research. The Committee is emphatic in its opinion that the War-time Social Survey is an essential service, performing useful work, and that on the whole the lessons of past experience have been learnt. The report administers a severe and well-deserved rebuke to the attack last summer on the Survey both in the Press and elsewhere, but also provides yet another warning of the way in which sectional interests or prejudices, sometimes inspired by Departments of State, are still able to impede or frustrate action or inquiry desirable in the general interest.

The Survey was established under the auspices of the National Institute of Economic and Social Research, in order to guarantee the scientific status of the personnel and methods used. A member of the professorial staff of the London School of Economics was appointed director, and there was also a committee of scientific advisers who were consulted both about the lines on which an inquiry should be conducted and about the scientific validity of all reports. The Survey was housed in a separate building from the Ministry of Information, the names and addresses of the persons interviewed are never passed on to the Ministry, and not one of the staff of the Survey was a Civil servant.

By June 1940 these arrangements were working well, and although since the autumn of 1940 the work has no longer been carried out under the auspices of the National Institute of Economic and Social Research, the advisory committee has been abolished and the staff has been reduced, the remaining safeguards having been retained. Reports were no longer circulated outside the Ministry of Information, and the Survey was used only for work commissioned by other Departments. As a result of further reorganization in the summer of 1941, the Survey now works under the general supervision of the head of the Home Intelligence Section of the Ministry of Information, under the control of the Director, Home Division. Its present constitution and activities were stated in NATURE of February 21, p. 214.

The Survey interviewers, who are all women, are selected with the greatest care, with particular emphasis on their intelligence, conscientiousness and trustworthiness. They are given careful training as well as exact coaching in the subject to be investigated, and the questionnaires are drawn up with the help of the advisory panel and the Department for which the inquiry is being made. The Ministry of Food and the Board of Trade are the Departments which have made most use of the Survey, the estimated expenditure for which for the current financial year is about £40,000.

The Select Committee is satisfied that the costs are not excessive and comments on the continuous use of the Survey, but it stresses the importance of laying down a carefully considered policy and planning the work. It emphasizes, secondly, the importance of great care in the choice of subjects to be investigated. The Survey should be used for factual inquiries which are necessary to guide a Ministry in some particular policy, and not for inquiries which attempt to assess morale. No inquiry should be begun without careful consideration as to its real necessity. The success or failure of an inquiry depends almost entirely on the interviewers, and no relaxation of the present standards should be entertained. Finally, and somewhat surprisingly and unconvincingly, the Committee recommends that the Survey should not be connected with or controlled by any one Department, but should accordingly be transferred from the Ministry of Information and placed under the direct authority of a member of the War Cabinet, for which purpose the Lord President of the Council is suggested, as being already responsible for scientific matters.

THE PROBLEM OF THE AUTONOMY OF LIFE

Science versus Materialism
By Prof. Reginald O. Kapp. Pp. vi+280. (London: Methuen and Co., Ltd., 1940.) 10*s.* 6*d.* net.

THE title of this book is rather misleading, since its main theme is an exposition of the author's 'philosophy' of vitalism, versus a scientific description of the phenomena of living organisms in terms of the existing concepts and laws of physics and chemistry. In this connexion he appears to be a 'materialist', that is, when he is contrasting the phenomena of life with what he calls the "material Universe", by which he seems to denote inanimate things. His great argument here is that living organisms cannot arise solely from the action of "matter on matter". He admits that the laws of physics and chemistry are operative in living organisms, but holds that they do not fully determine the "pattern" of life. This, according to him, is "doubly determined", that is, determined not only by the laws of physics and chemistry but also by "something else". This something else is "non-material".

Lest the ordinary reader might fall into the error of supposing that this "new light" amounts to a return to the Platonic doctrine of ideal forms, Prof. Kapp is careful to point out that the Platonic forms were applied by Plato to inanimate as well as animate things, whereas he (Prof. Kapp) intends his "immaterial something" to apply only to the "patterns" presented by living organisms. He does not refer to the Aristotelian entelechy, but no doubt that ancient ghost would suffer the same fate as the Platonic form, though Prof. Kapp's immaterial something looks very much like a confused mixture of the Aristotelian "final cause" and "formal cause". So what, according to the author, is his philosophic solution of the age-long problem of life? Being an engineer, he finds his mental haven of rest in one blessed word, "specification". The patterns of life unfold and repeat themselves according to some non-material, pre-determined and pre-conceived "specification". The molecules of matter, according to the author, do not *in this case* "shake down" into positions or states determined solely by their motions and intermolecular forces. No, no—there is always the "specification" to guide them to something better than that, just as the blue-prints of the engineer's drawing office direct the pattern maker, the foundry man, and the machine tool operator. Indeed, Prof. Kapp has no great objection to a living organism being regarded as a sort of machine, for "matter acting on matter could never produce a machine".

This oft-repeated argument against the possibility of living organisms arising from matter acting on matter rather reminds one of du Nouy's argument concerning the enormous improbability of a living organism arising out of a "material", that is, inanimate system in statistical equilibrium. Nobody with any knowledge of science would ever suppose such a thing. Both Prof. Kapp and Dr. du Nouy have forgotten the potency for producing order residing in the disequilibrium between the 'hot' radiation of the sun's photosphere and the relatively cool surface of this planet, though Schrödinger pointed out a number of years ago that no consideration of the problem of 'living organization' which left out of account the sun's enormous store of 'organized' energy could possess any scientific value. It may be pointed out to the author that the existence and activity of a living organism depend absolutely on the presence in its environment of certain chemical substances which are *not* in equilibrium, this disequilibrium (and consequent potency for producing order) being a direct consequence of the previously mentioned disequilibrium of radiation and matter. It is a curious and instructive fact that, in his yearnings for a "non-material entity", an electrical engineer should have failed to consider the part played by the electro-magnetic field and electro-magnetic radiation.

Prof. Kapp tilts at a number of people whom he calls "biologist-philosophers", among whom one may mention L. Hogben, J. Needham and J. B. S. Haldane. What he particularly dislikes about these biologists is that they *will* persist in the endeavour to describe the phenomena presented by living organisms in terms of the existing concepts and laws of physics and chemistry, that is, they do not invoke the aid of any metaphysical entity, whether entelechy or "specification". Now, Prof. Kapp admits that these biologist-philosophers are quite reasonably good, *qua* biologists. Where they err is in their lack of knowledge of the real nature of physico-chemical science! They might, however, retort that Prof. Kapp's knowledge of physico-chemical science is rather peculiar, to say the least of it, when he omits all consideration of one very pertinent *non-material* entity, to wit, radiant energy. But they possess a stronger argument even than that, namely, Prof. Kapp's "philosophy" of modern physico-chemical science, which is expounded in his discussion of "The Material Universe". Here one can detect the ominous effect of certain semi-popular expositions of modern physical science on the naïve mind of an engineer. Hearken, please, to the portentous words of warning with which the author introduces Section III (the *author's* version of the "Material Universe"): "if physicists were to describe what they find in Nature instead of what they have invented, they would sum up their observations in the words: Chaos, everywhere chaos". To this one can only say, "Eddington, O Eddington, behold what thou hast done!" Or should one blame the "Paycock"? For Prof. Kapp, the atoms and molecules represent no "repeated patterns", indeed no objective patterns at all, for they are the inventions of the minds of the physicist and chemists. His primary object in this section is, of course, to demolish the "objective reality" of what he calls the physicists' "material" world, so that he (Prof. Kapp) may be in a position to point out triumphantly to the wicked "biologist-philosophers" that they are trying to construct the "objective reality" of the living organism out of the stuff of pure thought. The elementary mistakes and logical fallacies of this section of the book are very obvious, and are strongly reminiscent of some of the 'popular science' of the Sunday Press.

It would, however, take too much space in a brief review to discuss in detail the author's fantastic views on *his* "Material Universe", or his subsequent demolition of the "philosophy of emergence". He gets fiercer and fiercer as he proceeds: *L'appetit vient en mangeant.* Enough has probably been said to give any potential reader an outline of the "new light" which the author seems to think he has shed on the question of "vitalism". In the opinion of the reviewer, however, he has made no contribution to philosophy or to science.

There does, indeed, exist a problem of the "autonomy of life", a problem which is at least as old as the writings and observations of Aristotle. This is really a part of the epistemological problem of the description of our knowledge. It is quite a wise and practical policy of the wicked "biologist-philosophers" to find how far they can go in describing the phenomena presented by living organisms by means of the existing *and rapidly developing* concepts, methods, and 'laws' of physics and chemistry. But, of course, this does not mean that fundamentally new *scientific* concepts and new logical methods of thought will not be necessary for the ultimate autonomous description of our knowledge of the phenomena of living things. The ancient concept of teleology, for example, with its implied concept of 'purpose', may perhaps be replaced in time by a sort of *teleochronism*, that is, actions at a distance in time, to be described by some new form of mathematics, or at least by integral and integro-differential equations and Volterra's theory of functionals, wherein the nuclei may be historical time-functions, descriptive of an internally determinate pattern of action. The discussions of Niels Bohr on the autonomy of the description of our knowledge of life, especially the application of his principle of "Complementarity" (which is essentially a fundamentally new mode of thought) to this problem, are highly significant and valuable. In any event, the *scientific* description of the "finalism" and pattern-unfolding of life will bear no resemblance to the crude and empty idea of an engineering "specification". Science does not advance by the simple invention of such sonorous substantives (unlike certain forms of philosophy). Indeed, Prof. Kapp's form of "science" reminds one very strongly of the German metaphysical idealism of the romantic Schelling-Hegel period; and perhaps Goethe might have welcomed it at Weimar! It was, however, the advance of real science in the nineteenth century which killed the fantastic *Naturphilosophie,* that weaving of imaginary worlds out of sonorous substantives devoid of verifiable meaning.

There are certain incidental errors in the text: Clerk Maxwell, not Clark Maxwell—a curious mistake for an electrical engineer to make; in several instances, J. S. Haldane and J. B. S. Haldane are comically confused with one another; it will be news to Dr. E. F. Armstrong that he is "the late E. F. Armstrong"—the author probably means his father, the late Prof. H. E. Armstrong.

In conclusion, when one compares the jaunty word-spinning and dialectical jumble of Prof. Kapp with the mystical verbalisms about time written by another engineer, one is tempted to revive, in modified form, an ancient saw: *Ne faber ultra machinam.*

MAGNETOCHEMISTRY

Magnetism in Relation to Chemical Problems

By Dr. K. N. Mathur. (Lucknow University Studies, No. 8.) Pp. vi + 185. (Lucknow: Lucknow University, 1940.)

MAGNETOCHEMISTRY is a branch of chemical physics in which interest has re-awakened of recent years. In no small measure has this been due to the considerable output and variety of work by Indian workers, and more particularly by Sir Shanti S. Bhatnagar and his collaborators. Bhatnagar has not only initiated, directed, and obviously inspired work in this field, but also he collaborated, in 1935, with the author of the monograph under review in writing "Physical Principles and Applications of Magnetochemistry". Several other texts have been published within the last decade, but there is still a large number of physical chemists (or is it, nowadays, chemical physicists ?) who would welcome a compact, clear, and concise account of what may be called post-Pascal magnetochemistry.

The present volume was written to fulfil this need. The first nineteen pages introduce the subject and deal with various methods of measuring magnetic susceptibility. A discussion of diamagnetism follows and occupies seventy pages. Langevin's theory of diamagnetism and van Vleck's quantum-mechanical theory are reviewed. Ionic susceptibilities, their evaluation by various means from experimental data and their calculation, are discussed, but it is questionable if so much space should have been given to Fajans's theories of deformation of ions. The additivity of diamagnetism and constitutive correction factors are next discussed and lead to applications of diamagnetism in valency problems, in liquid mixtures, addition compounds, polymerization, and in solid solutions and mixtures.

Paramagnetism is dealt with in fifty-seven pages (pp. 91–147) under the following headings : Langevin's theory, intrinsic molecular field, paramagnetism and quantum theory, paramagnetic substances and the influence of temperature and crystalline fields on them, iron group and complex salts, including a discussion, rather extended for the size of the monograph, on general theories of valency. A short chapter of six pages on magnetism in relation to chemical equilibria completes the subject-matter.

Then follow thirty-two pages of references, indexes, and advertisement of other works in the same series ; this seems to be an unduly large proportion of space to devote to these matters, particularly as only one reference, out of the 144 given, refers to work published after 1937. Much interesting work has been published since then, and its non-inclusion is one serious defect in the monograph. Unfortunately, there are others. The proof reading has been very badly done, with the result that typographical errors are frequent ; for example, "sudstances", "struture", "alipahtic", "invarient", "hysterisis", "principle quantum number". Much more irritating, and serious, are errors in mathematical expressions, confusion of symbols, omission of integration limits, and incorrect signs.

While the printing is clear and the format convenient, the style is variable and often careless. The frequent omission of the definite or indefinite article jolts the reader. So also does the use of "analysis" as a plural noun and of "maxima" and "minima" usually, but not always, as singular nouns (*vide* p. 87, which bristles with examples). Ungainly constructions need not necessarily convey wrong meanings, but several which do might be quoted from the monograph ; one must suffice : on p. 23 we read "*In case* [my italics] the atom possesses an initial magnetic moment the small value of the diamagnetic susceptibility may be entirely masked. . . ." Finally, the reviewer feels that he will not be alone in wishing that the statement on p. 12, that water is "easily obtainable in a pure form" were, in fact, really true.

Workers in the field of magnetochemistry will find this book insufficiently up-to-date ; to recommend it to students would be inadvisable, if not dangerous.

TOPOLOGY

Lectures in Topology

The University of Michigan Conference of 1940. Edited by Raymond L. Wilder and William L. Ayres. Pp. vii+316. (Ann Arbor, Mich. : University of Michigan Press ; London : Oxford University Press, 1941.) 3 dollars.

THERE is an amazing difference of opinion concerning the importance of topology. Some claim that it is a new type of mathematical thinking, which goes to the heart of qualitative spacial relations, makes complicated analysis intuitively simple, throws light on differential and functional equations, opens a new era in dynamics, and is applicable to problems of electric circuits and of the constitution of chemical compounds. Yet others regard it as a highly specialized subject which can be safely ignored even by geometers, and point out that topologists have not yet solved the apparently elementary four-colour map problem which has been discussed for more than a century.

Topology, formerly called *Analysis Situs*, is the theory of such properties of geometrical figures as are unaltered by stretching or bending (without tearing or joining). From this point of view a sphere is equivalent to an ellipsoid, but differs from an anchor ring. The fundamental problem is to find the invariants. One of the oldest results is the Descartes-Euler relation between V, E, F, the number of vertices, edges, and faces respectively of a polyhedron, namely, $V - E + F = 2$. Instead of a polyhedron, we may take V points on an ellipsoid, and by joining them up in pairs by E arcs divide the surface into F polygonal areas. Then $V - E + F$ is a topological invariant called the *characteristic* and has again the value 2. If we replace the ellipsoid by an (unbounded) surface of *genus* p, for example, a sphere with p holes through it, we get $2 - 2p$. Surfaces may also be classified as *orientable*, if a positive sense of rotation can be assigned consistently at all points, or *unorientable*, and for topological equivalence two surfaces must agree in this respect as well as in characteristic.

However, experts regard all this as merely the infancy of topology. The whole outlook was changed by Poincaré (from 1895), whose definitions and methods, particularly those involving matrices, are fundamental in the modern treatment. His work was n-dimensional and highly abstract, and later writers have still further refined it by introducing the postulational treatment of abstract spaces and the theory of aggregates. The contributions of L. E. J. Brouwer (from 1911) are of great importance. For the last twenty years, topological research has been pursued with enthusiasm in the United States, Poland and the U.S.S.R., but neglected in Great Britain.

The book under review gives the proceedings of the Topology Conference held at the University of Michigan during June 24–July 6, 1940. Twelve lectures are reported in full, and there are summaries of the shorter papers. The first lecture is by Prof. S. Lefschetz, whose well-known book "Topology" is almost indispensable as an introduction to modern work. Other lectures are by R. L. Wilder, N. E. Steenrod, S. Eilenberg, H. Whitney, S. S. Cairns, P. A. Smith, L. Zippin, S. MacLane and V. W. Adkisson, O. G. Harrold, jun., L. W. Cohen, and E. W. Chittenden. They are difficult to summarize for the non-specialist reader, because the subject has made such great progress in America that the problems on which experts are now working are so remote from the simple starting points.

A STEEL-MAKER'S AUTOBIOGRAPHY

Knotted String: Autobiography of a Steel-Maker

By Harry Brearley. Pp. ix+198. (London, New York and Toronto: Longmans, Green and Co. Ltd., 1941.) 10*s*. 6*d*. net.

THE author of this unconventional autobiography is known to many as the inventor of stainless cutlery steel, and to metallurgists as a practical steel maker, a trenchant critic at meetings of the Iron and Steel Institute, and as the writer of several excellent technical books. Those books contain the fruit of long experience in the melting and working of steel and in the conduct of laboratory research, expressed in language of great simplicity and directness, suggesting the hand of a master of English. They have nothing of the aridity of the ordinary text-book. It is therefore interesting to see how a boy, brought up in one of the dreariest parts of industrial Sheffield, came by his peculiar gifts.

The back-to-back houses of Ramsden's Yard must have been unattractive enough; yet the account of life in them pictures a condition of poverty but not of misery, relieved by much neighbourliness and good humour. Brearley's father being a crucible steel melter, the boy, following various casual occupations for a short time only, and receiving only a bare minimum of schooling, became familiar with the small and grimy workshops in which crucible steel, then the aristocrat of steels, was melted and cast. A cellar boy has leisure to study both technical operations and human nature, and this one was a keen observer of both. By good fortune he became bottle-washer in the laboratory of an analytical chemist, an ascetic who had known great poverty, but had managed to study chemistry at home and abroad. One of the peculiarities of this employer, of whom Brearley always speaks with gratitude, accounts for the strange title of the book. With his encouragement, the young assistant became an enthusiastic student, working at science in a night school and in laboratory hours. How he passed from Sheffield dialect to his limpid English style it is less easy to see. From bottle-washer he advanced to the position of assistant, paying the premium of £50 from his weekly wage of 20s. When this was doubled he married, gave popular lectures on science, became an ardent social reformer, and made his first appearance as a writer of scientific articles.

In 1904 he took up an appointment in Riga, where he stayed for four years, managing a laboratory under difficult conditions and acquiring, by hard experience, much knowledge of the treatment of steel and of human material. The Lettish workmen were ignorant and politically restless, and strikes and the revolution of 1905 added themselves to the technical obstacles which arose. How they could be overcome by good humour, common sense and sympathy can be read between the lines of the narrative. In the last part of the Riga period Brearley acted as manager, and then returned to Sheffield to set up a research laboratory for the firm which employed him.

The Riga experience had shown the advantages of such scientific helps to industry as the thermocouple, and in the treatment of such special products as naval armour plate and high steel tools there was ample room for more scientific control, in which this laboratory was a pioneer. In the course of experiments on rifle barrels, with the object of lessening erosion, a steel with a high proportion of chromium was prepared and was noticed in the laboratory to be unusually resistant to chemical reagents. The suggestion that it might be suitable for cutlery was not received with enthusiasm, and it was not until 1914 that a Sheffield cutler became interested and together with the inventor worked out the means of making table knives from the new steel, the difficulty being that the process of hardening was radically different from that used for ordinary cutlery, so that in the beginnings there were many failures. No patent had been taken out, and the subsequent negotiations as to the ownership of the invention make a rather sorry story. A lawsuit in the United States established the originality of the invention and involved a visit to America which left pleasant memories.

In consequence of these disagreements, Brearley left his employers and joined the firm with which he has since been associated. Travels in other countries, including Russia, and partial retirement, bring the story to a close, but there are final chapters containing the author's thoughts on many matters, metallurgical and other. One conclusion on which he insists repeatedly is the value of the experience of the practical man. The old steel worker who judges the quality of steel by the appearance of its fracture and by the feeling as it is worked under his hammer cannot express his valuation in quantitative terms, and his expressions may seem crude to the academically trained metallurgist, but he may have the root of the matter in him. Examples are given of specifications hampering industry because certain limits of chemical composition had become a fetish and had been allowed to overrule the experience of those who had to work the steel.

In another book, "Steel Makers", which vividly describes the old crucible process, the author has suggested means for enabling students to gain a practical knowledge of the operations they hope to control, and throughout both books stress is laid on the pleasure which may be felt in the work of one's hands, whether it be in chemical manipulation, in the working of clay, in carpentry, or in the mending of boots, all of which are referred to in this narrative. The reader feels that he has made the acquaintance of a skilled craftsman, a lover of good literature, of one who can look back with cheerfulness on his early difficulties, and who through varied experiences has attained to a ripe wisdom which leaves him tolerant of much, but not of social injustice.

C. H. DESCH.

SOME ASPECTS OF ALGAL CHEMISTRY*

By PROF. I. M. HEILBRON, F.R.S.
Imperial College of Science and Technology

WHEN I first approached this subject now some eight years ago our knowledge of the lipoid constituents of the Algæ, especially the carotenoid pigments and sterols, was exceedingly meagre. A partial survey of the algal pigments had been made by Kylin[1], but in the light of the precise knowledge of the lipochromes of the higher plants the pigments described by him required re-examination, the more so as his method of detection was purely qualitative and it is uncertain whether the carotenoids described represent distinct chemical individuals. As regards the occurrence of sterols among the Algæ no information whatsoever was available. In view of the recognized importance of these lipoids in relation to physiological factors, and bearing in mind the accepted botanical relationship between colour and classification, it seemed of importance to study both classes of compounds in detail.

Although as yet we have been unable to examine the whole field, we have so far investigated Algæ selected from seven of the eleven classes into which Fritsch[2] classifies them. In the interim, contributions from other laboratories have provided information regarding the pigments of some of the remaining classes, with the result that we now have a clear picture both of the occurrence and structures of these algal constituents. At the same time, as will be shown later, considerable progress has been made in our understanding of the physiological role of the carotenoids in relation to sexual reproduction.

Chlorophyceæ

We have now examined nine individuals from various orders of the Chlorophyceæ or Green Algæ, and in every case carotene and leaf-xanthophyll (mainly lutein) have been detected[3]. *Trentepohlia aurea*, a strictly terrestrial alga, requires special mention, as it is one of the richest sources of carotene hitherto described (compare also Tischer[4]). On the other hand, we have found that xanthophyll is only present in this alga in minute amount whereas in other Chlorophyceæ the xanthophyll-carotene ratio is 2–5 : 1, being thus of the same order as in the higher plants[5,6]. Another interesting observation is that Trentepohlia, unlike other Green Algæ, is wholly deficient in sterol, and in this respect resembles members of the Myxophyceæ. Our examination of the yellowish-green alga, *Zygnema pectinatum*, has revealed the presence of fucoxanthin, which pigment is normally confined to the Phæophyceæ. As no abnormality in the life-cycle or habitat of this alga is known, this raises the question as to whether the presence of this unusual xanthophyll is revealing the phylogenetic past or is forecasting some impending change.

Apart from these exceptions our survey of the carotenoids strongly supports the view held by most algologists that the terrestrial plants originated among the more advanced members of the Chlorophyceæ. Additional weight to the above view is provided from the sterol angle, for we now find that sitosterol, the characteristic sterol of the Phanerogams, is also common to the Green Algæ.

Xanthophyceæ

Unfortunately we have only been able to examine one member of these yellow-green Algæ, the common mud-alga *Botrydium granulatum*. β-Carotene has been definitely identified as the main epiphasic pigment, while in the complex hypophasic lipochromes we have observed the presence of a pigment having well-defined absorption maxima at 4750 A. and 4470A. and giving a strong blue colour with 25 per cent hydrochloric acid. The absorption values are in exact agreement with those recorded by Kuhn and Brockmann[7] for flavoxanthin, and it may well be that this pigment is characteristic of all the Xanthophyceæ. In this connexion it is interesting to note that the only information in the literature concerning the 'xanthophyll' of the Xanthophyceæ is the recognition that it gives a blue colour with concentrated hydrochloric acid. This could apply to either violaxanthin or flavoxanthin, but the spectrographic evidence excludes the former. The sterol present in *Botrydium granulatum* has been found to be sitosterol.

Chrysophyceæ, Bacillariophyceæ (Diatoms)

The only representative of the Bacillariophyceæ which we have so far examined is *Nitzschia closterium*. Of the Chrysophyceæ, a mixture of three members has been investigated, *Apistonema Carteri* Anand., *Thallochrysis litoralis* Anand., and *Gloeochrysis maritima* Anand. From both classes carotene, lutein and fucoxanthin have been isolated, and the analogy extends also to the sterols where we have observed only fucosterol[8]. This analysis supports the view that the Bacillariophyceæ and Chrysophyceæ have points of affinity. From the chemical evidence they would also appear to be related to the more primitive orders of the Phæophyceæ (Ectocarpales).

Phæophyceæ

Here the characteristic pigment is fucoxanthin, $C_{40}H_{56}O_6$. Apart from this pigment, Willstätter and Page[5] record the presence of both carotene and xanthophyll in the Phæophyceæ, although the latter was only assessed colorimetrically and never actually isolated. In our investigations of the Phæophyceæ we have extended the survey to include members from various orders and find that, despite the great diversity in the life-cycles of the individual species, all reveal the most marked uniformity of pigmentation, with fucoxanthin as the main hypophasic pigment, lutein only being demonstrated spectrographically in the lower members. Another striking feature of the Phæophyceæ is the universal occurrence of fucosterol and total absence of sitosterol; this, again, sharply differentiates the Phæophyceæ both from other Algæ and from the higher plants.

Rhodophyceæ

In general agreement with Kylin[1] we find the lipoid pigments to be carotene and lutein in all members of the seven orders examined, while the normal sterol appears to be sitosterol. An unexpected abnormality has been observed in the case of *Polysiphonia nigrescens*, an alga of striking red-black colour, which contains both fucoxanthin and fucosterol in addition to carotene and lutein. This abnormality of pigment and sterol is curious, as

---

* Substance of the Eighth Hugo Müller Lecture delivered to the Chemical Society on October 16, 1941.

Polysiphonia nigrescens is morphologically a perfectly normal diplolbiontic member of the order Ceramiales. The closely related *Polysiphonia fastigiata* is quite regular in pigment and sterol, despite its parasitic habitat on the brown alga, *Ascophyllum nodosum*.

Myxophyceæ (Cyanophyceæ)

These Blue-Green Algæ contain a specific carotenoid for which the name phycoxanthin was originally suggested by Kraus and Millardet in 1866. A more detailed examination of a member of this class (*Calothrix scopulorum*) was made by Kylin who, using his capillary method, qualitatively noted carotene together with three other pigments to which he gave the names myxorhodin-α and -β and calorhodin.

In 1935 my co-workers and I isolated from the terrestrial alga *Rivularia nitida*, in addition to carotene and lutein, another epiphasic carotenoid in crystalline form, for which the name myxoxanthin was suggested[9]. The same pigment was also found in a related marine species, *Rivularia atra*, and later[10] in the freshwater member, *Oscillatoria rubrescens*, from which source a second new pigment, myxoxanthophyll, was also isolated. The quantity of material available has unfortunately precluded a detailed examination of the latter, but analysis has given the formula, $C_{40}H_{56}O_7$, while, from the tenacity with which it is retained by alumina on a column, it obviously contains, like fucoxanthin, a multiplicity of hydroxyl groups. Unlike myxoxanthophyll, myxoxanthin is epiphasic, being a typical carotenoid monoketone having the formula $C_{40}H_{54}O$.

Tischer[11] has independently examined the carotenoids of another blue alga, *Aphanizomenon flos-aquæ*, from which he isolated four pigments, principally an epiphasic lipochrome which he named aphanin and a hypophasic member, aphanizophyll. Of these, aphanin is seemingly isomeric with myxoxanthin, according to Tischer being derived from β-carotene and not from γ-carotene as is the case with myxoxanthin. It is thus clear that the Myxophyceæ synthesize their own typical pigment which differentiates the class quite sharply from other Algæ.

Another striking feature, which we have noted, is the complete absence of sterols; bearing in mind that there is a total lack of sexuality in this class, the question as to whether any correlation exists between the presence of sterols and sexuality naturally frames itself, and although no definite answer can at this stage be supplied, it opens up an intriguing avenue for further investigation. If any significance is to be attached to sterol content in relation to the physiological phenomenon of reproduction, the question of *Trentepohlia aurea*, of which mention has already been made, comes under review. Whereas, so far as is known, this alga is sexually normal, it nevertheless is now growing in a habitat unusual for a Green Alga and, moreover, the genus is normally tropical. It may be that the disappearance of sterol in both the temperate and terrestrial conditions forecasts an impending loss of sexuality. It is also perhaps not merely coincidence that the bacteria, which are also lacking in sexuality, are likewise totally devoid of sterols.

Euglenineæ

Together with the Green Euglenineæ, members are known which are deep red in colour (for example, *E. sanguinea*), due to the presence of a red pigment for long known to botanists as hæmatochrome. Tischer[12] has recently examined *Euglena heliorubescens*, a rich source of this red pigment which he calls euglenarhodon and which he claims is a tetraketone[13] isomeric with astacene, $C_{40}H_{48}O_4$, the characteristic pigment of the Crustacea. Kuhn, Stene and Sörensen[14] have independently isolated the same pigment from the red spores of the green alga, *Hæmatococcus pluvialis*, and have shown that it is actually identical with astacene. The natural pigment is not, however, astacene, but a closely related ester of a xanthophyll to which the name astaxanthin, $C_{40}H_{52}O_4$, is given, and which readily passes into astacene through aerial oxidation during hydrolysis.

The occurrence of astaxanthin in the Euglenineæ is of especial interest in view of the position occupied by these flagellates in bridging the gap between the vegetable and animal kingdoms. Its presence in *Hæmatococcus pluvialis* is more difficult to comprehend; it may be noted, however, that the red pigment is apparently not present in the normal green motile Sphærella, but only makes its appearance at the onset of the resting phase or with variation in constitution of its habitat. The occurrence of eyespots (stigmata) in nearly all motile cells of the Algæ merits attention. These appear as a reddish or brownish-red dot in the superficial layer of the cytoplasm and the pigment has for long been considered by botanists to be hæmatochrome. In view now of our more precise knowledge, there can be little doubt that it is actually either astaxanthin or astacene.

Pigmentation and Sexual Reproduction

This problem has been examined in great detail during the past decade by the botanist F. Moewus[15], first at the Kaiser Wilhelm-Institut für Biologie at Berlin, and later in association with R. Kuhn at Heidelberg. For the purpose of their researches use was made in the first instance of the unicellular green alga *Chlamydomonas eugametos f. simplex*, in which the male and female gametes are morphologically identical (isogamous). As grown on an agar medium the gametes are devoid of cilia, but if they are suspended in distilled water and illuminated, the cilia develop in the course of about three minutes and after irradiation for a further two minutes these begin to oscillate and the cell becomes motile. The same effect can be brought about in the dark, but here oxygen is necessary and the distilled water is replaced by 1 per cent of glucose. It can be induced by the addition of a cell-free filtrate of gametes which has already become motile in light to a suspension of a dark culture even in absence of oxygen. This latter experiment proves that a definite chemical substance has been released into the water by the action of light. This substance has been identified with almost complete certainty as the saffron pigment crocin[16], the digentibiose ester of the carotenoid acid crocetin, $C_{20}H_{24}O_4$, and has been shown to be effective in producing motility at the astonishing dilution of 1 : 250,000,000,000,000.

Even though the gametes have thus become motile, they are still unable to copulate, which property they only acquire on further prolonged illumination. Unlike the first, this second photochemical process is effected only by irradiation with blue or violet light, the active wave-lengths being the two mercury lines at 4358 A. and 4961 A. The period of illumination is specific, being shorter for the female than for the male gametes, while over-irradiation gives only inactive filtrates. That here, again, definite chemical substances are formed and discharged into the surrounding solution is shown by the fact that it is not essential to irradiate the sexual cells themselves in order to produce the copulatory materials. One can first illuminate a male or female cell suspension activated in the dark with glucose and oxygen, with red light (6463 A.) for one hour and then filter and expose the inactive 'red' filtrate (V) to the further action of short-wave light, when the copulatory substances are again formed. The time required for attainment of 'female properties' by the filtrate is from 20 to 30 minutes ($K_{\text{♀}}$); after a longer time it becomes unable to confer on female 'dark' cells ability to copulate. After sixty minutes, however, the filtrate acquires the property of rendering male 'dark' cells active ($K_{\text{♂}}$), while after ninety minutes' irradiation the filtrate (K_0) becomes permanently inactive.

All these phenomena can be exactly reproduced if, in place of the filtrate (V), the light-sensitive pigment, *cis*-crocetin dimethyl ester, is employed. Under the influence of light this is converted gradually into the *trans*-form and it has been found that for this particular race of Chlamydomonas the material conferring copulatory activity on the female 'dark' gametes is a mixture of three parts of *cis*- and one part of *trans*-crocetin dimethyl ester. For the male 'dark' gametes the ratio is three parts of the *trans*-isomer and one part of the *cis*-ester. The V-material is perhaps the labile *cis*-crocetin dimethyl ester and the $K_{\text{♀}}$ material the *trans*-isomer. The biological limit of activity of both esters is found at a dilution of 1 : 33,000,000,000 which, great as this is, is not comparable with the effect of crocin in bringing about cell-motility.

In a still more recent memoir[17] considerable light is thrown upon the question of control of sex. For this purpose the hermaphroditic green alga *Chlamydomonas eugametos f. synoica* was selected. If this is treated with a filtrate of male gametes of the diœcious strain all the cells become male, while, conversely, a filtrate of female gametes renders all the cells female. It thus follows that the gametes must also secrete substances (termones) controlling sex. Although the termones in the active filtrates have not so far been isolated, it has been ascertained that the relationship of gynotermone to androtermone is of the type glycoside to aglucone. The fact that, unlike glycosides in general, the female termone is hydrolysed by alkali suggested that it might be picrocrocin, and the physiological activity of this compound was demonstrated. Although the authors consider that safranal is identical with the natural androtermone, the corresponding gynotermone is shown to be a thousand times more active than picrocrocin, and this they attribute to the presence of a sugar residue other than glucose, and possibly gentiobiose. Perhaps the most outstanding feature of this brilliant series of investigations is the remarkable insight it provides of the versatile manner in which Nature utilizes one substance only, the carotenoid crocin (or the as yet undetected protocrocin), to carry out numerous sexual functions. Kuhn[18] has recently announced the existence of an enzyme in male gametes capable of effecting the fission of picrocrocin. This glycoside-splitting ferment is in all probability localized in the cell nucleus, and this he considers may be a fundamental constituent of the chromosomes and, indeed, may be actually identical with the gene M (controlling masculinity).

In *Chlamydomonas eugametos* we have been dealing with a species where sexual reproduction is isogamous, and I now wish to direct attention to the question of oogamous reproduction among Algæ. In this connexion the diœcious members of the Fucales, such as *Fucus serratus*, are especially convenient as large quantities of both male and female gametes can be obtained in a pure state. The numerous biciliated sperms contain a small yellowish chromatoplast, and the mature antheridia therefore appear orange-yellow, which colour they impart to the entire receptacle. It appeared to my colleague, Mr. P. W. Carter of the Botany Department, Aberystwyth, and myself that an investigation of the nature of this yellow pigment might shed light on the fundamental process of sexual reproduction. At the time this investigation was commenced we were not aware of the researches of Kuhn and Moewus, and in any event the problem is different, as here only the male sperms are motile. Our experiments[19] have been carried out with *Fucus serratus*, *Ascophyllum nodusum* and *Fucus vesiculosus*, and have revealed that the pigment present in the male gametes consists almost entirely of β-carotene. In direct contrast to the results obtained with the male exudate, the examination of the corresponding female exudate has revealed that the colour of the ova is due solely to chlorophyll and fucoxanthin. As β-carotene is to be observed only in the male gametes it may be that this carotenoid is bound up with their motility. Perhaps under the influence of light and in presence of oxygen the hydrocarbon becomes oxidized to crocetin which then acts in a similar manner as with Chlamydomonas. The association of carotene with sexual processes is further suggested by recent work carried out by Emerson and Fox[20], who have observed that in the case of the aquatic fungus Allomyces, the orange colour of the motile male gametes in the sexual phase is due to γ-carotene.

Another problem to be elucidated in connexion with the sexual process in these Fucaceæ is the mechanism whereby the motile male gametes become attracted to the egg. Kuhn and Wallenfels[21] have shown that in the case of the sea-urchin this is brought about by the ova secreting a compound, echinochrome A, into the sea-water. It may be that fucoxanthin plays a similar part in these algal ova or that something akin to echinochrome is secreted. This latter possibility is supported by the fact that we have obtained cell-free extracts of ova of *Fucus serratus* which attract the sperms. It is our intention to investigate these matters in greater detail at a more opportune moment.

FOUNDATIONS OF THE NEW WORLD ORDER

By SIR JOHN ORR, F.R.S.
Rowett Research Institute

POST-WAR economic reconstruction is neither possible nor desirable. We reconstructed after the War of 1914–18. The system wobbled in the world economic crisis of 1929; it has now crashed in the present War. Its doom is deserved. A system which, of set purpose in the interest of a few, limited the production and distribution of food and other necessities of life urgently needed by the vast majority of men, is incompatible with human welfare. With the old economic system goes its superstructure, the international political system under which we have suffered two world wars in one generation. The old world order is in its death throes.

Piecemeal planning for such limited objectives as the restoration of the sovereign rights of small States, the adjustment of political boundaries for a new balance of power or, in the economic field, for new trade agreements and the restitution of trade union rights, on the assumption that after the War things will be pretty much as they were before, is worse than a waste of time. It diverts men's minds from the real task, which is the building of the new world in which all men in all lands will enjoy the freedom from fear and freedom from want promised in the sixth article of the Atlantic Charter.

The old world, which had within it both good and evil, is undergoing a metamorphosis. The good and the evil are struggling for supremacy. The call of the new world is a challenge to the human race. Has man the higher spiritual attributes needed to build it? Has he the intelligence to recognize irreversible changes now taking place in human society and the goodwill to direct these changes along lines calculated to promote human welfare?

An evident irreversible change is the transition to a World State. Science has eliminated distance. To-day, the countries of the world are in closer contact than two adjacent counties in England were a hundred years ago. Phases of a World Government have been evolving rapidly since the time the first steamship crossed the Atlantic. Finance, trade, science and even sport have come under some form of international control, and Governments have united in organizations, such as those for the control of infectious diseases, and an international postal system. The last phase will be the organization of a properly constituted Government based on a sound world economic policy with a world police to maintain law and order. This will carry through and complete the task begun half-heartedly when the League of Nations was set up after the War of 1914–18.

The real issue of the War is whether the World Government will be the kind imposed by the Nazis in Europe, which means a throw-back to the more primitive form of social order based on slavery and maintained by brute force, or a democratic Government in which nations will co-operate for their mutual benefit.

The Nazis have an advantage in the struggle because they fully realize they are fighting for world dominion and they have created an enthusiasm among the German youth for their new world in which they will be the *Herrenvolk*. We, on the other hand, while willing to fight to the death to defend ourselves against Nazism, have no clear vision of the future to enthuse our own people and the people of all other lands for an offensive war as a crusade to establish the new and better world. We have not yet even reached agreement on the kind of world we are fighting for.

The only way to reach agreement is to go back to fundamentals. All men of goodwill would agree that the first duty of Government is to provide the necessities of life for the people governed. The material necessities of life are (1) food and (2) shelter, which includes a house, furniture, clothing and warmth. To these must be added (3) work, which is a psychological necessity. The British Commonwealth, the United States, the U.S.S.R., China and all the other nations opposing Nazism could reach agreement on a simple positive programme based on providing the necessities of life for the people.

This may appear a rather meagre programme. As a matter of fact, even in the wealthiest countries, we could not complete this programme in less than ten years. A third of the population in the United Kingdom and about an equal proportion in the United States do not enjoy food and shelter on the standard needed for health. In most other countries, the proportion of the population which has never been adequately fed or adequately housed is even higher. Among native races, for whose welfare Britain is responsible, only a relatively small proportion of the population have reached that economic level.

If every family had a home in which they could live in decency, food on the health standard and a feeling of absolute security that they would never fall below that level, we should have an economic and social foundation upon which we could begin to build a new world which, in time, would provide for a still fuller life.

This simple plan of providing for human needs on a health standard has the great advantage that we know what we are planning for. The needs are known. We can measure them and estimate the time it will take to provide them.

I have outlined elsewhere a national food policy which would fit in with the world plan and would enable post-war food relief for Europe to dovetail smoothly into a permanent policy. The scheme suggested would involve less interference with the freedom and initiative of the farmer and trader than was involved with the pre-war marketing board schemes.

While food can be planned on a world scale, housing varies so much with climate that it is a national problem. In Great Britain the only way to get all families housed in our day is by a temporary housing scheme. In Scotland, after seventeen years of Government housing schemes, during which 280,000 houses were built, there were still 250,000 families needing decent homes. This was the position just before the War. The number needed by the end of the War may be about 400,000. In England it will be more than 2,000,000. These families cannot wait for a home until we have completed plans for the better location of industry and for new towns. A *temporary* housing scheme, providing houses on a minimum standard of whatever material is available, should be undertaken immediately the fighting finishes. An advantage of a temporary scheme is that it would give time to see what industries are likely to be after the War and where they can best be located. Within, say, ten years, these houses could be replaced by more permanent and better houses. We need not worry about the waste involved in a temporary housing scheme. Our capacity for production after the War will be increased to such an extent that there will be difficulty in getting an outlet for the products. In any event, the waste of human life involved by existing slum conditions is more important than the waste of material.

As Mr. Roosevelt has pointed out, the standard of living of the masses of the people is so low that if we undertook to provide satisfactory homes and adequate food for everybody, there would be work for every man and woman seeking a job. But provision must be made for men temporarily out of employment, and every man, rich or poor, should be made to do some useful work. A National Service Corps would provide for this. The men in the Corps could be employed on national or local government work. Every man should be forced to serve for a year before he reaches twenty-one years of age. After a year's service, a man would be free to leave. He would also be free to return if he wished and could not find employment. After a man had served a number of years calculated to be sufficient to pay for the bare necessities of life on a health standard for himself and his family, he could retire and enjoy these with the same dignity and self-respect as a man drawing an endowment for which he had paid all the premiums.

This plan for adequate food, a decent home and security for every family would bring about a social revolution. Bringing food and housing among the poorest third of the population up to the standard for health would reduce disease and improve national health and physique. Poverty in the old sense of the term would be gone for ever. A great part of our social and public health services and most of our charities would become unnecessary. The unemployment problem would be solved. Every family would have security for a good home. For the first time in history, the common man would enjoy economic freedom and the means of attaining his full physical and spiritual manhood.

This plan would also lay the foundation for agricultural and economic prosperity. It is estimated that in the United States the production of the protective foods, for example, milk, eggs and fruit, would need to be increased from 15 per cent in the case of some to 100 per cent in the case of others. Similar increases are required for Britain and larger increases for most other countries. The production of this additional food would call for a great expansion of agriculture. To enable agriculture to produce the food needed the great majority of farms in Britain would need to be re-equipped. The same is true of almost all other countries, including the United States. The re-equipment of agriculture would provide an outlet for an enormous amount of industrial products. When production had reached a level which would supply human needs there will be a permanent increase in the trade in food and in the commodities exchanged for food. A food policy based on human needs would be the spear-head for agricultural and economic prosperity.

A policy of providing first for human needs, as outlined here, would be so revolutionary and so beneficial that it would be wise to concentrate on it and leave all industries not directly concerned with the necessities of life to the free play of private enterprise. This would provide for the flexibility needed for the adjustment of industry and trade to the advances of science.

This plan for building the new world from the bottom upwards would give expression to our growing spiritual idealism. Every great spiritual awakening calls for sacrifice. This plan involves sacrifice. In Britain those who already enjoy the necessities of life on a health standard—and that includes the well-paid workman—would need to stand back from the national table until those worse off are served. To accomplish the world food plan, the wealthy nations must give to the poor nations food, agricultural equipment and the other things needed to provide the necessities of life, not against a loan which would sink the poorer nations in debt, but on a world-wide lease-lend plan arranged by an international financial organization, the security of which would be guaranteed by all nations, including the poorest. The poorer nations would not be encouraged to pay interest in the form of money or exports which would delay the provision of the necessities of life on a health standard for the whole of their population. When they had reached that level, they could begin to pay their debt in money or in kind. The nations would find their spiritual and economic salvation in this policy of giving.

This may seem Utopian. It is merely the policy of the good neighbour. Any ordinary citizen would give food to a neighbour needing it, demanding nothing in exchange immediately. Until Governments in their dealing with each other reach the moral standard which regulates neighbourly relations, the world will never be free from war.

The adoption of this plan would remove the feeling of uncertainty and apprehension as to what is going to happen after the War. Everyone would know what they were fighting for and working for. The people in the occupied countries in Europe and even in Germany itself would know what our peace aims are. They could be told incessantly, day and night, that when our armies invade Europe they will bring the food ships with them, and that the United Nations will continue to send food and other things needed not merely for post-war relief but until each country, including Germany, is in a position to provide the necessities of life on a health standard for the whole population. We could, in terms which would carry conviction, call upon the people of all countries to join with the armies of the free to carry through the glorious revolution for the destruction of the forces of evil, and the establishment of a new World Order in which the nations will co-operate to bring freedom from the fear of war and freedom from want to all men in all lands.

QUANTUM THEORY AND DIFFUSE X-RAY REFLEXIONS

IN the article by Mr. G. D. Preston which appeared in NATURE of April 4, a descriptive account was given of the theory put forward by Sir C. V. Raman in a series of papers published in the *Proceedings of the Indian Academy of Sciences* to explain the extra spots on Laue and other types of X-ray photographs. We are here adopting a much more critical attitude.

Raman has emphasized the fact that when X-rays are scattered by a vibrating system, the scattered beam contains components of changed frequency. It is not, however, made clear either in the Symposium or in Preston's account of it that this is a consequence both of classical and of quantum theory. From the classical point of view it is the Doppler effect for the reflexion of X-rays by waves of atomic vibrations; in quantum language it is the transfer of energy from a photon to an acoustical quantum, or vice versa. This frequency shift has long been acknowledged by the thermal theory. Since the frequency changes are much too small to be observed, they are not of practical significance except in so far as they are intimately connected with the incoherence of the scattered rays, which is an essential feature of the phenomenon.

Raman also gives the impression (which is not refuted by Preston) that his theory is a "quantum" theory and that the thermal theory is a "classical" one. The exact opposite is the case. As Preston remarks, Raman's presentation is obscure, but it is clear enough that at no stage (except when he introduces the effect of temperature change) does Raman make use of quantum mechanisms at all. He does not attempt, for example, to calculate the intensity with the help of transition probabilities. The thermal theory, on the other hand, although originally presented, nineteen years ago, in a semi-classical form, has since been given a strictly quantum-mechanical basis. The facts are that Raman's "excited vibrations" must exist (either from a classical or a quantum point of view), but that their contribution o the scattering is extremely small as compared with the effect of the thermal vibrations.

All the experiments described by Raman and his olleagues are in entire accordance with the thermal heory, but experiments on metals and on the "forbidden" reflexions of diamond, which he did not ttempt, definitely prove that his theory cannot ccount for the facts. We have outlined some of our rguments in the following communications (written efore we had read Mr. Preston's account) and have laborated them in papers to be published elsewhere.

M. B.
K. L. and H. S.

Sir C. V. Raman's theory of the extra spots on aue photographs having now been published in etail, I wish to deal with the theoretical aspect, as believe it is now possible to show exactly where aman's statements are incorrect.

(1) Raman assumes that the extra spots are due ot to the acoustical (low-frequency) branch of the ibrational spectrum but to *monochromatic infra-red brations*.

This assumption contradicts the results of lattice ynamics, which show that the elastic spectrum nsists of different branches, each of N vibrations N number of unit cells), uniformly distributed in ciprocal space (co-ordinates: components of wave ctor $\mathbf{q}$). In order to justify this contradiction, aman points out that lattice theory uses the method the 'cyclic lattice' (replacing the boundary contions by the postulate of periodicity in a parallel-iped of N cells), a method which he says is not oved but arbitrarily invented to simplify the athematical treatment. As a matter of fact, it is t proved, apart from a simple example (chain of ual particles) and a limiting case (continuous edium). These cases show, however, that the cyclic ethod is not arbitrary, but mathematically reasonle; and it is also well confirmed by its applications r example, conductivity of metals). As Raman tacks the validity of the method, in particular for e optical branches, I have rigorously solved the problem of a finite di-atomic one-dimensional lattice (chain of two alternating particles); the result is, of course, uniform distribution of the frequencies in both branches and the same law for their dependence on wave number as given by the cyclic method.

The intensity of X-ray scattering of all branches will be incoherent and proportional to N. Raman's contention that the scattering due to an excited infra-red vibration will be coherent and proportional to N^2 has no theoretical justification whatever.

(2) Bisheshwar Dayal attempts to support Raman's assumption of monochromatic infra-red vibrations by calculations about the *specific heat* of metals, which he contends cannot be represented by a Debye function but needs additional terms of the Einstein type. This suggestion is not new; it was given in my book "Dynamik der Kristallgitter", published in 1915 (formula 200, p. 77), where I showed that the optical branches of the lattice oscillations are narrow bands which for the calculation of specific heat can be approximately replaced by one frequency. It is clear that no support for Raman's hypothesis can be obtained from a formula previously derived from lattice dynamics.

(3) Raman considers the *sharpness of the lines* observed in the optical Raman spectrum of crystals as a proof of the monochromatic character of the infra-red vibrations. It is not. Lattice theory explains it as a consequence of the optical selection rule: emission of light waves will not occur for every case of resonance, since the electric moments of the different cells of the crystal are in general out of phase; it is restricted to long waves for which the phases in a large group of cells are equal, and this corresponds to an extremely small region of the reciprocal space near the point $\mathbf{q} = 0$. To each 'optical branch' of frequency there belongs only one sharp 'optical resonance'. (I regret if the term 'optical branch' has led to this misunderstanding; but the facts are clearly stated in several publications.)

(4) Raman's proof that *the acoustical branch cannot produce sharp spots* is, shortly, the following: The scattering is proportional to the mean square of the amplitude of vibration, $\overline{\xi^2}$. On the other hand, the mean potential energy of an oscillator of angular frequency ω, $\frac{1}{2}\,\omega^2\,\overline{\xi^2}$, is equal to half the mean total energy $\frac{1}{2}kT$, $(\hbar\,\omega << kT)$, hence $\overline{\xi^2} = kT/\omega^2$. Raman replaces ω by $2\pi c/\lambda$, where λ is the wave-length of the elastic wave, c the velocity of sound. Thus he obtains the scattering of the acoustical branch proportional to $kT\lambda^2$, which is a smooth function and cannot give rise to spots.

The fallacy of this argument lies in the assumption that c is a constant. It is not. In fact, the relation between λ and ω is involved. ω is a periodic function of the components of the wave vector $\mathbf{q}$ (length $q = 1/\lambda$). Consider as illustration the oscillations of a set of parallel equidistant planes in the lattice (spacing a) which will be roughly the same as that of a chain of equidistant mass points (linear lattice); it is well known that the frequency in this case is $\omega = \omega_0\,|\sin(\pi a/\lambda)\,| = \omega_0\,|\sin(\pi q/b)\,|$, where $b = 1/a$ is the lattice constant of the reciprocal lattice. The dynamical theory of the scattering leads to the same result as de Broglie's quantum condition: the intensity is enhanced if the difference of the momentum vectors for the incident and reflected photon is equal to the momentum of the acoustical quantum, or $2\,Q\,\sin\,\delta = q$, where $Q = 1/\Lambda$ is the wave number of the X-ray. (As the left-hand term may have any value, q cannot be restricted to the domain $0 \leqslant q \leqslant b/2$, or $2a \leqslant \lambda \leqslant \infty$, for which $\omega(q)$ assumes all possible values.) Taking for the mean square amplitude Raman's approximate expression kT/ω^2, the 'scattering power' is proportional to

$$S(q) = \frac{kT}{\omega_0{}^2 \sin^2(\pi q/b)},$$

and the intensity for the direction δ is $S(2Q \sin \delta)$. $S(q)$ is a periodic distribution in the 'reciprocal space' q; it has sharp peaks (infinities) at the points of the reciprocal lattice $q = 0, b, 2b, 3b, \ldots\ldots$ These correspond to the Bragg reflexions; for $2Q \sin \delta = nb$ is the same as $2a \sin \delta = n\lambda$.

If all possible sets of reflecting planes are simultaneously considered, the formulæ are more involved, but the principal features unaltered: the scattering power $S(\mathbf{q})$ is a function of the three components of the wave vector $\mathbf{q}$, and the scattered intensity due to the vibrations is $S(\mathbf{Q}' - \mathbf{Q})$, where $\mathbf{Q}$ and $\mathbf{Q}'$ are the wave vectors of the incident and scattered beam (of practically equal length). $S(\mathbf{q})$ consists of additive terms each corresponding to one branch of the vibrational spectrum, and these have peaks (infinities) for the acoustical branches in the points of the reciprocal lattices (which correspond to the Laue spots); but the terms for the optical branches are quite smooth functions, as for these $\omega(\mathbf{q})$ does not approach zero.

Hence the correct theory attributes the observed extra spots to the acoustical vibrations—just contrary to Raman—and this is well confirmed by experiments of Lonsdale and Smith on various metals.

The optical branches may give broad but relatively weak intensity maxima halfway between Laue spots because $\omega(\mathbf{q})$ has minima there (in the linear case for $q = \frac{1}{2}b, \frac{3}{2}b, \frac{5}{2}b, \ldots.$).

(5) Raman claims that the extra spots are due to a peculiar *new type of quantum effect*. His theory, as now made known, is however completely classical, whereas the so-called 'thermal' theory based on lattice dynamics (which Raman rejects) is developed strictly on quantum principles. The only point where Raman introduces a quantum consideration is in respect of the temperature dependence of scattering produced by his monochromatic infra-red vibrations. With the help of strange reasoning he obtains a formula which is in fact (apart from a factor of 2) identical with the formula for the energy of an oscillator with zero-point energy, according to Planck. Now this quantity determines the intensity also in the theory based on lattice dynamics.

Venkateswaran tried to confirm Raman's assumption by deriving the characteristic frequency in the Planck formula from the observed temperature effect of the extra spots, and to compare it with other determinations of infra-red vibrations (Raman effect). These observations had to be made on extra spots well separated from the corresponding Laue spots and would therefore in any case refer to oscillations of relatively high frequency. All the experiments showed was that for carborundum the oscillations were of higher frequency than those for a soft organic crystal, a result which the theory of lattice dynamics undoubtedly predicts, because of the differences in the quasi-elastic forces in the two substances.

(6) In order to explain the *specific intensity of extra spots* corresponding to different Laue spots, Raman introduces special assumptions about the directions of his monochromatic waves. Lattice dynamics provides the explanation without any assumption, by expressing the scattering power $S(\mathbf{q})$ as a function of the quasi-elastic forces between the atoms. These can be approximately expressed in terms of the elastic constants (Zachariasen, Jahn, Sarginson). Jahn has shown that the elastic anisotropy of cubic crystals leads to a characteristic anisotropic distribution of $S(\mathbf{q})$ around each point of the reciprocal lattice; Lonsdale and Smith have used Jahn's formula very successfully for representing their observations.

The extra spots are not, as Raman assumes, in contradiction to lattice dynamics, but provide a powerful method of checking it in every detail.

University of Edinburgh. MAX BORN.

Prof. Born and Miss Sarginson[1] have pointed out that according to the quantum mechanical calculations of Ott (1935) and also from the point of view of Placzek's quasi-classical theory, the excitation by the X-ray energy of characteristic crystal vibrations (analogous to the Raman effect in light scattering would only be expected to give X-ray interference effects entirely secondary in importance to those o the thermal vibrations. Ott[2] suggested, however, tha in regions where a Bragg reflexion would normally be forbidden, the Raman effect might possibly giv an observable reflexion, and questioned whether th 222 reflexion from diamond might not be such a instance.

This suggestion has recently been revived by Si C. V. Raman[3] (who does not, however, either admi the secondary importance of the excited vibration or refer to Ott's paper) and has been worked out i quantitative detail by P. Rama Pisharoty[4], on th basis of an excited 1,332 cm.$^{-1}$ oscillation *normal t one set of* (111) *planes only*. This procedure we believ to be incorrect and misleading, since such oscillation if excited at all, will certainly take place with equa probability normal to all the {111} planes. However, Pisharoty makes the following predictions fo a perfect diamond set for reflexion at the Brag angle appropriate to each plane in turn:

(1) There is no 222 Bragg reflexion, but tha there is a 222 extra reflexion (which he alternate calls a modified, quantum or Raman reflexion), th intensity of which is roughly equal to that of the 11 extra reflexion.

(2) There is no 220 extra reflexion, or alternatively, that if there is, it will be *very* much weak than the 111 extra reflexion. He reports that D Nilakantan has failed to find such a reflexion i spite of many trials.

(3) There is no 200 Bragg reflexion, but th there is a 200 extra reflexion. The intensity of th extra reflexion he estimates to be about one thi of the 222 intensity, but in so doing he has neglect to allow for the difference in Bragg angle. Actuall his theory would make them nearly equal.

We have investigated these reflexions with th greatest care, and have fully established the followi experimental facts:

(1) The 'forbidden' 222 reflexion is in every re pect similar to a Bragg reflexion and has none the peculiar characteristics of an 'extra' reflexio It appears sharply at the appropriate Bragg an (for our *D*(2) diamond its intensity was about 0 of that of the 111 Bragg reflexion), and when t angle of setting is varied it disappears complete even when the exposure given is several times long as that required to record the 111 extra refle

ions with appreciable intensity in positions of equivalent mis-setting. The 222 reflexion was examined in both possible diamond orientations ($[1\bar{1}0]$ axis vertical) and no sign whatever was found of the detail that would correspond to intensity spikes along cube directions in reciprocal space (that is, of any effect geometrically analogous to the 111 streaks and triangles).

(2) The $\{220\}$ planes, in all orientations, do give extra reflexions, both primary and secondary[5], which are at least half as intense as the 111 extra reflexions. We cannot understand Dr. Nilakantan's failure to find them.

(3) There are no reflexions of any kind from the (200) planes, of intensity comparable with that predicted, or even as much as 1 per cent of that value.

We used both direct and monochromatized (copper $K\alpha$) radiation from a 5-kw. tube. In order to avoid all possible errors of setting, we took series of Laue photographs at 0·2° intervals, and also 1° and 5° oscillation photographs. Exposures varied from 5 seconds to 2 hours. Using X-radiation monochromatized by reflexion from the (001) plane of urea nitrate, a weak reflexion was observed in the 200 position; its intensity was about 0·01 of that of the 222 reflexion (exposures of one hour and 30 seconds were required to record the two with comparable intensities) and about 0·0003 of that of the 400 Bragg reflexion. It was certainly due to the 400 reflexion of wave-length $\lambda \text{Cu}K\alpha/2$. Such 'unwanted' radiation is unavoidable in any monochromatized beam if the monochromatizing plane used has a second-order reflexion, and it sometimes amounts to as much as 1·6 per cent of the λ component[6]; for precise work it should always be estimated and allowed for. (Such a $\lambda/2$ component probably accounts for the doubtful 100 reflexion on a monochromatic photograph of sodium chloride, referred to by C. S. Venkateswaran[7].)

P. Rama Pisharoty and R. V. Subrahmanian[8] observe that the absence of the 111 extra reflexions (of the secondary kind) in type II diamonds[9] is due to the probable mosaic structure of these rare specimens. There are not, they suggest, sufficient cooperating planes in each block for the subsidiary phenomena to appear. In a reply to this suggestion it may be pointed out:

(1) That the 222 reflexion (which they have claimed to have the same origin as the 111 subsidiary reflexions) does appear quite strongly in type II diamonds. The larger value of the 111/222 intensity for such diamonds as compared with that for type I is due to the very much greater 111 intensity, not to a decrease in 222.

(2) That the secondary effects were observed so strongly, with our powerful X-ray equipment, for some type I diamonds, that had the effect for type II diamonds been even 0·01 as intense it would almost certainly have been found.

(3) That the temperature-sensitive diffuse spots (primary extra reflexions) which are certainly due to X-ray diffraction by elastic vibrations, appear equally strongly for both types of diamond. Yet according to Raman[10] and Venkateswaran[11], the relative diffraction effect due to elastic vibrations should, on their theory, vary proportionately to the size of the crystal block, whereas that due to the excited characteristic vibrations should not.

(4) That soft organic crystals and soft metals such as sodium and lead, which are undoubtedly mosaic in structure, show excellent extra reflexions.

Pisharoty and Subramanian suggest that in the diamond orientation we used ($[1\bar{1}0]$ vertical), the [001] direction was tangential to the sphere of reflexion, thus accounting for the absence of extra reflexions along that direction for the (220) and (113) planes. A little consideration, however, shows that it was not. The [001] direction was more nearly normal to the sphere of reflexion than either [010] or [100] directions along which 220 extra reflexions *were* found, and only a little less so for the 113 reflexion. We thought it unnecessary in our former communications to stress the fact that the absence of extra reflexions along certain directions for some diamond planes is an intrinsic property of the diamonds and not an effect due to the geometry of the experiments.

Finally, we wish to point out, as an experimental fact proved beyond question[6], that the integrated intensity of a Bragg reflexion is *not* proportional to N^2 (N = number of lattice cells *in the crystal*) as Raman repeatedly implies[12], but to the volume of the crystal, that is, to N. Born's theory gives the integrated intensity of an extra reflexion as also proportional to N. In practice it is always integrated intensities that are compared.

OBITUARIES

Dr. George Senter

The death of Dr. George Senter on March 14 brings to a close an eventful life as man of science and administrator. Let us recall the main events of his history. Born in 1874 at Kildrummy, Aberdeenshire, he was educated at the Universities of London, Leipzig and Göttingen. He obtained his first teaching post in 1904 as lecturer on chemistry at St. Mary's Hospital Medical School, and became head of the Chemistry Department, Birkbeck College, London, in 1913. Five years later, when the outcome of the War of 1914–18 was in the balance, Senter became principal of the College and so inaugurated a period which must be regarded as one of the most important in the history of that institution.

Birkbeck College grew out of the London Mechanics' Institution—founded in 1823 with Dr. George Birkbeck as first president. The College still maintains the honourable and ancient association of poverty and scholarship in that it serves the student who has to pursue learning and earn his living at the same time. Senter was the type of administrator who sees possibilities rather than difficulties and dangers. He grasped boldly and imaginatively the opportunities before him, with the result that when he retired in 1939 the College had become a school of the University of London, and on a fine site in Bloomsbury, next to the Senate House of the University, the foundations of a new college building were laid. Senter had good cause for happiness in the outstanding success of his principalship. Besides guiding the internal affairs of the College, Senter took a prominent part in the larger world of the University. As an active member of the Senate his shrewd judgment was appreciated and his work on committees and boards earned him the respect and affection of his colleagues.

George Senter possessed one of the rarest and most precious of gifts in a man of science or administrator —the gift of lucid exposition. This he turned to good account in his well-known books, "Outlines of Physical Chemistry" and "Text-book of Inorganic Chemistry," which have delighted and helped a generation of chemists. In view of his fine record in administration there may be a tendency to forget his eminence as a man of science. Senter realized at an early date that kinetic investigations would be necessary for the satisfactory elucidation of the problems connected with the phenomenon of the Walden inversion. He carried out a number of pioneer investigations and had he been able to devote himself to this work there seems little doubt that results of great theoretical interest would have emerged. Actually this early work on chemical kinetics in which he was engaged when he became principal of Birkbeck College is now regarded as fundamental, and after some twenty years forms the basis of one of the most rapidly developing branches of physical chemistry.

Although Senter was a bachelor he was not a self-centred man. He had a true and understanding heart associated with a tolerant mind and a happy gift of humour. For relaxation he turned to the peace and joy of his garden and the countryside. In the minds of the hosts of his friends there will ever remain the remembrance of a shrewd and kindly man who had a sincere desire to serve his fellow-men.

W. Wardlaw.

Dr. J. G. Myers

John Golding Myers was born near Rugby in Warwickshire on October 22, 1897. In 1911 his parents moved to New Zealand. There he did brilliantly at school, winning a scholarship to Victoria University College, Wellington. During the War of 1914–18 he came to Europe with the New Zealand Expeditionary Force. Returning to Wellington he completed his studies and obtained the B.Sc. and M.Sc. degrees.

From 1919 until 1924 Myers was employed as entomologist in the Biological Division of the New Zealand Department of Agriculture, where he did excellent work on the cattle tick and other pests. In 1924 he won the coveted honour of an 1851 Exhibition Scholarship for New Zealand and elected to go to Harvard University. There he worked at the entomological laboratory of the Bussey Institution, eventually obtaining the degree of Sc.D. In 1925 Myers came to England to represent the New Zealand Government at the Second Imperial Entomological Conference. Afterwards he went to France at the request of his Government to study the natural enemies of the pear leaf-curling midge. In the following year he was appointed to the staff of the Imperial Institute of Entomology to organize the breeding of parasites of injurious insects for export to the Dominions and Colonies. He did splendid work on the parasites of the blow-fly and of the timber-infesting wood-wasps, which made possible their export to Australia and New Zealand. Myers next visited Australia to investigate the passage of dried fruit from the vine to the consumer and was successful in tracing the sources of insect infestation. In 1928 he went to Trinidad to study the possibilities of the biological control of sugar cane pests. He travelled all over the West Indies and to Guiana and Surinam in search of parasites, and his report, published by the Empire Marketing Board, is a mine of information not only on insect pests and their parasites but also on the general ecology and agriculture of the countries visited.

Myers' work in the West Indies continued up to 1934, when he joined the staff of the Imperial College of Tropical Agriculture in Trinidad. Here he undertook a number of private expeditions at the request of various planters, collecting and studying the ecology of insect pests in unknown parts of British Guiana, Venezuela and Brazil.

In 1937 Myers was appointed economic botanist to the Government of the Anglo-Egyptian Sudan, his task being to survey the economic possibilities of the southernmost province of Equatoria with a view to its future agricultural development. Only preliminary reports of this work are available, but they cover a great variety of subjects and show the usual thoroughness of his approach and the broadness of his vision. It was fated that this task should not be completed, for he was killed in a motor accident near Amadi, Equatoria Province, on February 3.

Apart from his many papers on biological control, and related topics, Myers produced a large number of works on Hemipterous insects which showed him to be a morphologist and systematist of the highest order. Myers' versatility, broad ecological outlook and great experience in many parts of the world made him the most outstanding economic entomologist of his generation. In his death at the early age of forty-four, applied biological science has lost one of its most brilliant investigators. He leaves a widow and two small daughters in British Guiana.

W. E. China.

Sir William Bragg

Qu'il me soit permis d'apporter un hommage français à la mémoire de Sir William Bragg, dont la mort, suivant de près celle de J. J. Thomson, endeuille aujourd'hui la science anglaise.

J'avais appris à connaître et à admirer l'œuvre de Sir William Bragg, il y a de nombreuses années, alors que je faisais mes premières armes de chercheur au laboratoire de Madame Curie. Son livre sur la Radioactivité avait une place d'honneur dans notre bibliothèque, et le volume, très usé, témoignait de l'utilité de l'ouvrage : il était toujours entre les mains de quelque chercheur ou de quelque étudiant.

J'ai eu l'honneur d'être reçu par Sir William Bragg lorsque je parvins en Grande Bretagne après m'être évadé de France, en juin 1940. Je n'oublierai jamais l'amabilité de son accueil, ni les paroles de sympathie, si directes et si profondément senties, qu'il prononça à l'égard de notre malheureux pays.

Je suis sûr d'être l'interprète de tous les hommes de science français, forcés au silence par leur situation, en priant Sir Lawrence Bragg et la Royal Society d'accepter leurs condoléances émues et le témoignage de leur profond attachement à la mémoire du grand disparu.

A Free French Scientist.

NEWS and VIEWS

Gardiner Chair of Chemistry at Glasgow

After a connexion of almost forty years with the chemical department of the University of Glasgow, Prof. T. S. Patterson retires from the Gardiner chair of chemistry at the end of the present session, thus bringing to a close a period of teaching activity which has coincided with a period of great expansion in the University Chemical Department. As a research worker Prof. Patterson's chief interest lay in the subject of optical activity, and more especially in the physico-chemical aspect of the subject. His investigations on the effect of solvent, temperature and wave-length of light on the rotatory power of the derivatives of tartaric acid have produced data which will be of great value to future workers, while his modification of the "characteristic diagram" of Armstrong and Walker has simplified the co-ordination of rotatory dispersion phenomena. But in recent years Prof. Patterson has become more absorbed in the historical aspect of chemistry, and in this field he has found fuller scope for his literary ability than was possible in the mere recording of the results of personal experiment. The results of his researches on the lives and work of the earlier chemists have been embodied in excellent articles contributed to the *Annals of Science* and to *Isis*. He has always taken an interest in student activities and was a constant attendant at meetings of the "Alchemists", a student chemical society the well-being of which he had much at heart.

Dr. J. Monteath Robertson has been appointed to the Gardiner chair of chemistry in the University of Glasgow as from October 1, 1942, in succession to Prof. T. S. Patterson, whose resignation takes effect then. Dr. Robertson, who is forty-one years of age, was educated at Perth Academy and the University of Glasgow, where he graduated B.Sc. with special distinction in chemistry in 1923 and M.A. in 1925. His post-graduate research work also began there, and he has since received the degrees of Ph.D. and D.Sc. from the University. During the tenure of a Carnegie research fellowship Dr. Robertson worked at the Royal Institution in London under Sir William Bragg. During 1928–30 he was in the United States as a Commonwealth Fund fellow and worked in the University of Michigan and the Gates Chemical Laboratory, Pasadena. On his return he joined the staff of the Davy Faraday Laboratory of the Royal Institution and remained there until his appointment in 1938 as senior lecturer in physical chemistry in the University of Sheffield. He has published many papers dealing with the chemistry of natural products, X-ray diffraction methods, molecular dimensions and structure, etc.

Dr. Robertson is best known for his beautifully finished determinations of the structures of conjugated organic compounds by the X-ray study of minute single crystals. In 1932 he mapped the electron density distribution in anthracene crystals by means of two-dimensional Fourier analyses along three principal directions, and showed that the chemist's structural formula represents with considerable nicety the arrangement of atoms in the plane molecule. By designing an apparatus which would enable an absolute comparison to be made photographically between the intensities of the incident and reflected X-ray beams, and by devising various mechanical methods of speeding up the formidable amount of computational work involved, he was able to make similar studies of many other compounds, including those of the dibenzyl and the phthalocyanine series (partly in collaboration with Miss I. Woodward). He proved that the interatomic distances in these compounds are dependent upon the bond characters, and provided a mass of reliable experimental data for testing theoretical calculations based upon energy relationships. His direct determination of the structures of nickel and platinum phthalocyanines not only gave valuable information concerning the stereochemistry of those metals but also showed that the usual 'trial and error' method of determining phase constants can be dispensed with in special cases. His latest work (in collaboration with Dr. A. R. Ubbelohde) has concerned the lengths of hydrogen and hydroxyl bonds and their changes with crystalline dimorphism, temperature and deuterium substitution. Few present-day scientific men have succeeded in obtaining so much accurate numerical data of fundamental importance to organic chemistry.

Suppression of Culture in Norway

We are informed that a petition, signed by fifty-two members of the Royal Society of Science and Letters of Göteborg, has been presented to the Swedish Minister for Foreign Affairs asking him to intervene on behalf of three Norwegian members of the Society who have been imprisoned and subjected to severe treatment in Norway. A translation of the petition reads: "Three foreign members of the Royal Society of Science and Letters of Göteborg have already for a considerable time been deprived of their liberty. They are known to us as eminent scientists and scholars and are citizens beyond reproach. As far as we know, none of them has been convicted of any crime against the laws of their country by a legal court of justice or even accused of any criminal offence. To all of us their fate has given great pain. The fact that Prof. Seip (of the University of Oslo), for reasons unknown to us, has been subjected to cruel treatment has further increased our anxiety on their behalf. We members of the Royal Society resident in Göteborg herewith apply to your Excellency to do everything in your power in order to set our fellow-members at liberty and enable them to resume their studies and research." It is to be feared that this petition will be of little avail, though it reflects the views of the men of science of neutral countries, and is much to their credit.

Scientific Research in Sweden

Extensive research activity is going on in Sweden, in order to find substitutes for products which can no longer be imported owing to the War. One of the most important centres for this research is the Physical-Chemical Institute, Uppsala, headed by Prof. The Svedberg. The Institute has now lost all the foreign research workers who used to study there, with the exception of one Swiss; nevertheless the staff has been doubled. Extensions have in particular been made to departments dealing with the many present supply problems, of which the chemical aspects fall within Prof. Svedberg's own department, namely, the giant molecules. The work with different kinds of synthetic rosins and cellulose-derivatives is now progressing on a large scale. Among other objects of research may be mentioned bread. Experiments are being made to find a means of replacing imported hard wheat, which was formerly used to improve the baking qualities of bread made from Swedish native soft wheat. Investigations are also being carried out on synthetic rubber. The work has proceeded so far that the product has been evolved in the laboratories of the Institute, although it is too early yet to say whether domestic production can be started and its probable extent.

One of the foremost technical means of research of this Institute is the Svedberg ultra-centrifuge, which has become of the utmost importance to science. The rotor of this centrifuge is given a speed of up to 70,000 revolutions per minute by a number of oil turbines. The Institute also houses such instruments for research as one of the world's largest electro-magnets and a neutron generator, both of which have been made in Sweden. In the biochemical section the experiments for locating and cultivating infantile paralysis virus and tuberculine on the basis of a new method for analysing mixtures through molecule splitting are carried on under the direction of Prof. Arne Tiselius, who has devised this method. The object in the first place is to obtain a pure form of virus. The stoppage of the import of apes for these experiments for a while threatened the workers with the loss of indispensable test animals, but it is stated that their replacement with rats has now proved acceptable.

Quality Control in Manufacture

AN article by H. Rissik on "Quality Control in Manufacture" in the *Electrician* of March 27 reviews the principles of the subject with special reference to the use of control charts. The theoretical foundations of the method were laid down originally by Prof. R. A. Fisher, and the technique itself, which was originated in the Bell Telephone Laboratories of the United States, has been applied successfully for more than twelve years throughout the various manufacturing organizations of the Bell system. The technique of quality control is, briefly, one of inspection-cum-production, based on known statistical methods which have been applied successfully in other fields, and it has proved to be a valuable aid to manufacturing concerns engaged on repetition work. Its advantages include reduction in inspection costs and in rejects, attainment of maximum benefits from quantity production and of uniform product quality even though the inspection test be destructive, immediate applicability as part of inspection routine, and utter simplicity of application.

Fundamentally, the problem is one of controlling variability in some directly measurable quality characteristic, for example, dimension, weight, tensile strength, electrical resistance, hardness, etc. In practice this means analysing the variability observed and comparing it with some objective standard. Thus, provided a product is known beforehand to be stable, limits may be assigned within which practically all observed values of the variable quality characteristic are expected to lie. If measurements on a succession of piece-parts, produced supposedly under the same essential conditions, are found to give dimensional values lying outside these limits, then it may be inferred that they were not, in fact, so produced, that is, the production process was not stable in the first place. This leads to the very heart of quality control as a technique enabling preventive action to be taken before trouble develops; and the basis of this is the so-called quality control chart which is, in effect, a continuous graphical record of product quality. The article discusses the use of the control chart and makes reference to the recent British Standards Institution publications, *B.S.* 600–1942 and *B.S.* 1008–1942.

Electrical Instruments

IN his chairman's address to the Meter and Instrument Section of the Institution of Electrical Engineers (*J. Inst. Elec. Eng.*, 89, Pt. 1, No. 13, January, 1942), W. Phillips surveys the design and performance of electrical instruments. Development since the 1890's has been twofold: first in widening the limits of measurement, and secondly in accuracy. Switchboard moving-coil instruments are now available to give full-scale deflection for 10 μ amp. or less, and ammeters having a range of 30,000 amp. are in use. In voltage, the range is from a few micro-volts, with apparently no upper limit, the sensitivity of D.C. moving-coil instruments now being limited only by the non-magnetic quality of the moving system. The standardization of frequency at 50 c./s., and its close regulation by supply undertakings, has fostered the design and use of testing apparatus for the measurement of power factor, peak factor, and current; and also of voltage testing sets and similar apparatus for use at fixed frequency. The Electricity Supply (Meters) Act created an immediate demand for standard and sub-standard instruments of all types, large sums being expended by supply authorities in equipping meter-testing stations. Great improvements in wattmeter performance have been made, particularly in the reduction of self-heating error and D.C./A.C. change-over error.

One of the recent major troubles with which instrument makers have had to cope is the almost complete stoppage of supplies of sapphire jewels. An English company now manufactures sapphire jewels from rough boules, but it cannot yet meet the demand. Substitutes are being provided, consisting of nitralloy steel jewels for meters, while for instruments a specially hard glass jewel is available requiring no expensive or elaborate manufacturing plant. The jewels at present being manufactured are mainly for use in miniature instruments, a small number only having been made for larger instruments.

Electric Heating of Premises

MR. W. GILCHRIST, in a paper read recently before the Institution of Electrical Engineers on the above subject, deals with the various methods of applying electricity to space-heating, water-heating and sundry special applications with particular reference to large-scale space- and water-heating installations. The author records the fundamental principles of design and some of the results obtained from certain methods of heat application which do not, in some respects, follow existing practice. The possible economic limits of using electricity for direct heating are related to the capacity of both commercial and domestic buildings, there being a definite limit to the size of such installations both from the consumer's and supplier's points of view. Details are given of certain combinations of radiant and convection heating to achieve maximum comfort conditions at a lower cost to consumer and supplier than other existing methods. Examples are given of installations using a combination of thermal storage, local thermal storage and direct heating, and a method of applying water-heating to large installations is described which considerably improves the overall efficiency. A domestic electrification policy is outlined with special reference to space- and water-heating for working-class houses, and it is suggested that future policy in the domestic electrification of houses should be based on the use of a proportion of solid fuel for heating and water-heating.

Bee-keeping in War-time

At a lunch of the Backs to the Land Club held on March 25, Dr. C. G. Butler, of the Rothamsted Experimental Station, gave an address on the place of bee-keeping in the national economy. As Dr. Butler pointed out, it appears to be the common idea that the value of the honey-bee lies in the honey it produces. From the point of view of national economy, however, its function as the pollinator for fruit and seed crops is of prime importance. Honey has not been found to contain any measurable quantity of vitamins, but its invert sugars make it very readily assimilated by the human body. It is therefore of special value in treating cases of shock; also invalids and young children. Dr. Butler stressed the undesirability of too many beginners taking up bee-keeping at the present time. The shortage of supplies, in his opinion, is such that established bee-keepers should have first claim on such supplies, rather than the novice knowing nothing at all about bees. There is evidence that in many places where large orchards, or areas of insect-pollinated seed crops are planted, there are insufficient wild pollinating insects present for full production. Dr. Butler urges that, at the present time, greater efforts should be made to use honey-bees for pollination by making them available by the transfer of stocks to such areas where they are most needed.

Wilhelm August Lampadius (1772–1842)

At the time when geologists and mining students flocked to the Freiberg Mining Academy in Saxony, and when Gottlob Werner was at the height of his fame, a twenty-year-old chemist because a member of the staff, and from that time onwards for half a century, he taught, wrote and experimented with great success. This young chemist was Wilhelm August Lampadius, who in his fourteenth year had been apprenticed to a Göttingen apothecary. Born at Hehlen in Brunswick on August 8, 1772, Lampadius lost his father, a pastor, at an early age. Apprenticed by his mother at Göttingen he devoted his spare time to study and was befriended by the university professors J. F. Gmelin and Lichtenburg. At the age of nineteen he entered the service of the metallurgist Count Sternberg of Bohemia. With the Count he made a journey to Russia and in the Count's laboratory made experiments on electricity and heat. His talents becoming known to Werner, he was given a post at Freiberg and on the death of C. E. Gellert (1713–1795) he was made professor of chemistry. In this situation he assisted German industry in many ways. He spread a knowledge of Lavoisier's discoveries, and made researches connected with mining and metallurgy, chemical manufactures, agriculture and meteorology. Especially important among the books he published was his handbook on smelting. A man of estimable character, respected alike by his friends and colleagues, he died at Freiberg on April 13, 1842) in his seventieth year. His place in the Academy was taken by Karl Friedrich Plattner (1800–1858), the chief of the royal department of assaying and an authority on the use of the blow pipe.

Earthquakes Registered at Kew

During February 2–March 5 four large earthquakes were registered on the seismographs at Kew Observatory. The first, on February 2, began recording at 17h. 15m. 28s. U.T., possibly from an epicentral distance of 1,500 km., though long waves were not pronounced and the shock appeared to possess some of the deep-focus characteristics. On February 16 a strong shock began recording at 18h. 27m. 31s. U.T., possibly from an epicentral distance of 13,300 km. It finished recording at 20h. 00m., having lasted some 1h. 32·5m. The third earthquake, on February 21, began recording on all three components with *iP* compressional at 07h. 20m. 14s. The tentative calculated epicentral distance was 9,300 km. The shock appeared to be normal, had a maximum ground amplitude at Kew of 72 μ, and finished recording at 09h. 40m. U.T. The third disturbance, on March 5, began recording near 19h. 59m. 56s. U.T., though the start of *iP* was somewhat confused by microseisms. The epicentral distance may have been near 8,200 km., the long waves were of small amplitude, and the shock finished recording at 21h. 10m. U.T.

Announcements

On the joint recommendation of the presidents of the Royal Society and the Institution of Civil Engineers, the James Alfred Ewing Medal for 1941 has been awarded to Dr. F. W. Lanchester. The Medal is awarded annually for specially meritorious contributions to the science of engineering in the field of research.

The first Sir Joseph J. Thomson Memorial Lecture of the Chemical Society will be given by Lord Rayleigh, in the Lecture Theatre of the Royal Institution on April 16 at 4.30 p.m.

Prof. B. K. Malinowski, University professor of anthropology in the London School of Economics who now holds the position of Bishop Museum visiting professor of anthropology in Yale University, has been appointed professor of cultural anthropology at that University as from July 1.

Prof. Emil Abderhalden, professor of physiology at Halle and for many years president of the German Academy of Natural Sciences at Halle, has had the latter appointment extended for another ten years.

At a meeting of the Quekett Microscopical Club, held on March 21, the following officers were elected: *President*, Mr. W. E. Watson Baker; *Hon. Librarian*, Mr. C. Best; *Hon. Curator*, Mr. C. Sidwell; *Hon. Secretary*, Miss C. Arnold.

The following awards in respect of the year 1941 were made at the annual corporate meeting of the Institution of Chemical Engineers on March 27. The Osborne Reynolds Medal, for meritorious work accomplished for the advancement of the Institution during the year, to Dr. A. Parker, honorary editor and recorder of the Institution; the Moulton Medal (in gold), for the best chemical engineering paper of the year, of a mature character, read before the Institution and published in the *Transactions*, to Mr. P. Parrish, for his paper "Modern Developments in the Design of Plant for the Concentration of Sulphuric Acid"; the Junior Moulton Medal for 1941 was not awarded; the William Macnab Medal, for the best set of answers submitted in the associate-membership examination during the year, to Mr. E. W. Pates.

Use of Soil Fertilizers in China

Beginning in 1935, this Department has been investigating the fertility of the soils of China, with especial reference to the limiting effect of plant food deficiencies, and to the possibility of increasing crop production by the use of fertilizers. The investigation is based in the first place on field experiments, chiefly 'NPK tests', consisting of modern factorial designs at two and/or three levels. The standard rate of application throughout is eight *catties* per *mou* (about 0·5 cwt. per acre) of nitrogen, phosphate and potassium (N, P_2O_5, and K_2O). The experimental crops are rice, wheat, maize, rape-seed, cotton, millet, barley, sugar cane, Irish and sweet potatoes, and mulberries (chiefly the first five). The experiments have been carried out either by this Department directly, or in co-operation with provincial institutes, universities, and other organizations. The field experiments are supplemented by laboratory chemical tests for 'available' nutrients in the soils of the experiments.

The results of more than 170 of these field experiments, widely scattered through fourteen provinces of China, are now available. The work is still continuing, and yield results already obtained are still being analysed, but although the investigation is thus incomplete, it is desired to put the broad results on record, in case the work should be interrupted. It is realized that the number of experiments is not large, in relation to the area covered (a consequence of the difficult conditions which have existed here since 1937), but none the less the general results are quite consistent within the various regions or soil groups, and it is believed that further extension of the work will not greatly alter the picture. It is thought that the findings will have some general interest to agriculturists and geographers, while the implications are important for the future of China.

Eighty-three per cent of the soils tested in the field experiments gave significant responses to one or more nutrients: in other words, soil fertility is likely to be limited by plant food deficiencies in at least four fifths of the soils of China. (Early statements about the high fertility of Chinese soils were usually based on a superficial acquaintance with the rich soils of alluvial plains and deltas; much of interior China consists of relatively poor, hilly, land.) Nitrogen deficiency was most general (74 per cent of the soils); next came phosphate deficiency (38 per cent); potash deficiency was uncommon (12 per cent), probably because of the general use of ashes and local manures. There were clear relationships between the great soil groups and nutrient supply or deficiency, which there is not space here to set out in detail. Briefly, the pedocal soils of north China (J. L. Buck's 'wheat region') were often deficient in nitrogen, but they were generally well supplied with phosphate and potash; the pedalfer soils of central and south China (Buck's 'rice region') were still more deficient in nitrogen, often seriously deficient in phosphate, and sometimes deficient in potash. The red and yellow earths were the most seriously nutrient-deficient soil groups, and those on which fertilizers were most strikingly effective in increasing yields.

Estimates were made of the probable extent to which crop production could be increased in China by using artificial fertilizers in addition to the present supplies of local manures and fertilizers (which cannot be much expanded). If artificial fertilizers were used only on soils where they were likely to be needed (on the soils which gave significant responses in these experiments), it would be possible to increase the total production of crops in China by between one third and one half, using the rates of application mentioned above. (The variability of the estimate depends on the weights to be applied to different crops and regions.) This estimate may be taken as applying to the part of China covered by Buck's "Land Utilization in China", with the exclusion of his 'spring wheat area'. The increase in production would be much greater in the rice region (about one half increase over present production) than in the wheat region (about one fifth increase).

Taking economic factors into consideration, and using the 1937 farm prices in east and north China as a basis, it can be said that if all farmers whose soils needed fertilizers applied what was necessary, at the standard rate, then on the average individual farmers would have a two-to-one chance of making a profit (that is, one farmer out of three would be likely to lose money). If only those farmers applied fertilizers whose soils were likely to give an economic response, on the basis of the field experiments, total crop production in China could still be increased by at least one quarter. Supposing that China developed her own fertilizer industry, and that fertilizers could be sold at prices comparable with those in the United States in 1937, then these estimates would be considerably increased. If all farmers with deficient soils used the necessary fertilizers, then each farmer would have at least a five-to-one chance of making a profit from his expenditure; if only those farmers used fertilizers who were likely to secure an economic response, total crop production in China could be increased by at least one third.

The bearing of these results on the population, food and economic problems of China needs no emphasis. While it may not be possible to take much action on them under present conditions, for the future they are equivalent in increased production to adding four or five new provinces to the seventeen or eighteen provinces for which these estimates may be expected to hold good. In connexion with the reclamation and resettlement of the poor soils of south-west China, too, the use of fertilizers is likely often to make the difference between success and failure.

Age Changes in Size of Muscle Fibres of the Marsupial Heart

As we have pointed out elsewhere[1], there is considerable evidence for believing that the conducting systems of mammalian and avian hearts (nodes and Purkinje fibres) are neomorphic developments, evolved in response to functional requirements in these homoiothermal vertebrates, and not remnants of more extensive tissue of similar structure in lower vertebrate hearts[2,3] or embryonic muscle[4,5].

We have hitherto based our conclusions on histological studies of the hearts of lower vertebrates, in which we have failed to find any nodal or Purkinje tissue. We have now striking corroboration that these tissues are specialized structures and not embryonic remnants from measurements of the fibre-size of various regions of marsupial hearts, *Macropus ruficollis bennetti*, fœtus (pouch state) and adult, and adult *Macropus giganteus*. The accompanying table shows the maximum breadth of the majority of fibres in each region; a small range of variation in size of fibre occurs in each case, but this is in no way comparable in magnitude with those differences between the specialized and ordinary heart muscle to which we have directed attention.

	M. ruficollis (fœtal stage) Fixed—10 per cent formalin. Stain—Van Gieson and iron hæmatoxylin	*M. ruficollis* (adult) Fixed—10 per cent formalin. Stain—Van Gieson and iron hæmatoxylin	*M. giganteus* (adult) Fixed—10 per cent formalin. Stain—Pyridine silver
Sinu-atrial node	8 μ	(Sinu-atrial node not present in block)	10 μ
Atrio-ventricular node	10 μ	10 μ	10 μ
Atrio-ventricular bundle (Bundle of His)	12 μ	36 μ	36 μ
Atria	4 μ	11 μ	16 μ
Ventricles	5 μ	12 μ	18 μ

It will be observed that, whereas the ordinary trial and ventricular muscle fibres increase markedly n size from the fœtal to the adult stage, the nodal ibres are fully developed in the fœtal stage. This uggests strongly that the nodal fibres are specially eveloped (for the initiation of the cardiac rhythm), hile the size of the ordinary heart muscle increases ith the increasing work (against peripheral resistnce) which this muscle is called on to perform. The odal fibres in the fœtus are larger than the ordinary trial and ventricular fibres, a condition which is eversed in the adult. This suggests that the nodal ibres do not constitute an embryonic stage in the evelopment of ordinary myocardium but attain full pecialization for their particular function early in fe. The large increase in size of the Purkinje fibres ith age can be correlated with the requirement for ore rapid conduction of the impulse in the larger eart.

A full account of the conducting systems of these nteresting hearts will be published elsewhere.

Extra Spots in Electron Diffraction Patterns

Many photographs have recently been published showing extra spots in X-ray diffraction patterns from single crystals. These extra diffractions are ascribed to thermal vibrations of the atoms or molecules in the crystal; they are close to the normal Laue-spot positions and comparable in size with the Laue spots. The close parallelism between the electron and X-ray diffraction phenomena leads us to expect that diffractions of this kind should also occur in electron-diffraction patterns, but although we observed[1] much more diffuse maxima two years before the work of Preston[2] directed attention to the X-ray extra spots, no extra spots of the X-ray type have hitherto been observed in electron diffraction, nor has the diffuse electron type been observed in X-ray patterns. It therefore appeared desirable to discover whether this distinction was of fundamental importance, or simply due to the difference in experimental conditions so far adopted. The absence of the diffuse electron type of maxima in X-ray patterns is apparently due to the experimental conditions[3], but we were unable to explain the lack of such extra spots in electron diffraction.

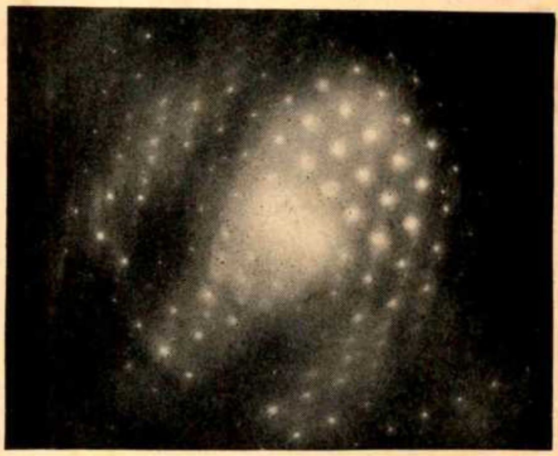

Fig. 1.

ANTHRACENE, SHOWING SHARP LAUE SPOTS, DIFFUSE, SLIGHTLY ELONGATED, EXTRA SPOTS AND DIFFUSE BANDS.

The recent clarification of the X-ray results has led us to re-examine some electron-diffraction patterns in which we had noticed apparently anomalous features. These we now find correspond closely to the X-ray extra spots. Thus, diffuse spots occur in regions where the sharper Laue spots are forbidden, as may be seen clearly in Fig. 1, obtained from anthracene with the electron beam practically parallel to [112]. The diffuse spots correspond to intersections of the sphere of reflexion with the reciprocal-lattice intensity regions, which are enlarged as a result of thermal vibrations in the crystal.

In very anisotropic crystals the intensity regions may become elongated in characteristic directions, and with suitable crystal orientations they may give rise to streaks in the diffraction pattern[4]. In the case of anthracene we have found in many patterns, including several published previously[1], a series of such streaks, the positions and directions of which indicate that the molecules vibrate with maximum amplitude at right angles to their length (Fig. 2).

We have also observed these phenomena in other aromatic compounds, as well as in long-chain hydrocarbons and their derivatives. We therefore conclude that the parallelism between the electron and X-ray diffraction phenomena also extends generally to the effects originating from thermal vibrations in crystals.

Open Packing of Spheres

AT the present time when economy of material is so important, the problem of the open packing of spheres possesses more than theoretical interest. The most open (or least dense) packing is unknown[1]. A number of systems have been described by Heesch and Laves[2] including one with a density of 0·056, which may well be the most open possible under the conditions which they have imposed upon themselves. But if the object be to obtain a homogeneous structure with minimum density, in which each sphere makes contact with three others, and which shall be in equilibrium (though not necessarily in stable equilibrium), then, discarding the condition that the assemblage shall be of the single-parameter type, it is possible to proceed as follows:

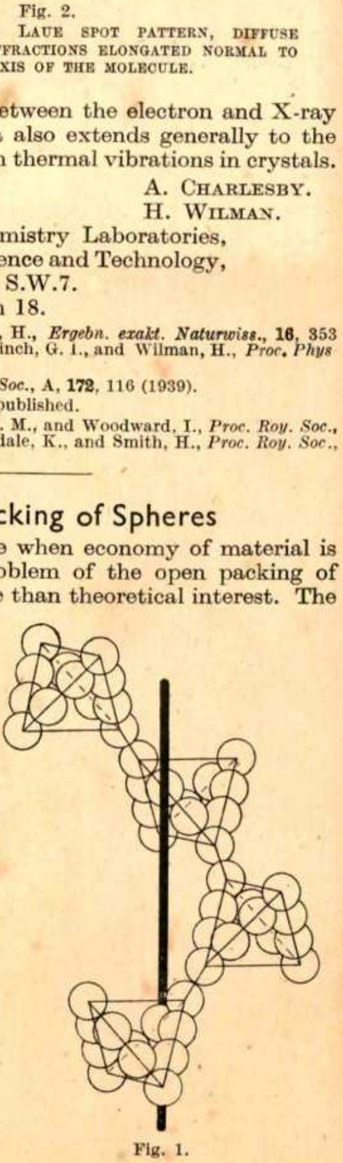

Fig. 1.

Take twelve equal spheres and arrange them in contact with their centres on four opposite edges of a regular tetrahedron. Take quantities of such tetrahedra and arrange them about a tetragonal screw-axis in such a way that a face of a tetrahedron is co-planar with a face of each adjacent tetrahedron, a plane of symmetry perpendicular to these faces being common to the two adjacent tetrahedra (Fig. 1). By extending the process systematically a series of tetragonal screws is developed, alternately right- and left-handed. Part of this tetragonal assemblage as seen from above is shown in Fig. 2. It has a density of 0·042.

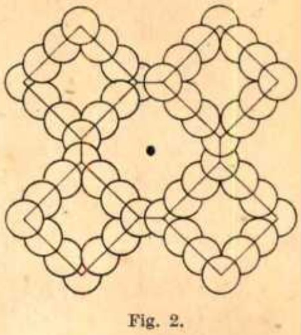

Fig. 2.

The study of a model of the lines of centres of the spheres in this structure, considered as a system of girders, may perhaps commend itself to engineers.

'Firmness' in Compression and Tension

ATTENTION was directed some time ago[1] to th applicability of Scott-Blair's equation, $\psi = s^{\beta}\sigma^{-1}t$ (s is shearing stress, σ is strain, t is time, ψ is firmness k and β are constants) for the 'firmness' of sof materials[2] to tests in tension as well as to tests i compression. This applicability was later extende to tests in torsion[3]. Some actual experimenta figures were published showing the comparison between tension and torsion tests results, but no figure have been given for comparative tension and compression tests. These were omitted as no good agreemen was obtained, apparently indicating the existence o experimental errors. It is now believed, howeve that the apparent anomalies are due to a fundament cause and not to experimental error.

		Bitumen 2	Bitumen 4	Bitumen
k:	extension	0·47	0·82	0·89
	compression ...	—	0·70	0·74
	torsion	0·48	0·85	0·82
log ψ:	extension	8·0	6·3	7·1
	compression ...	—	6·2	6·6
	torsion	7·9	6·6	6·9

A few typical results are given in the accompanyi table, whence it is seen that the values for both and log ψ are higher for tests in tension than compression. Torsion tests give values not precise corresponding with either of the other two methods, but approximating to the tension figures. They are definitely higher than the compression figures.

It has been suggested[4] that the differences may be eradicated by making allowance for the changing cross-sectional area of the specimen during test in the case of the extension tests, as this factor was ignored during early experiments and is automatically counteracted in the particular compression apparatus employed. Such correction may be made in tension experiments by calculating the strain on the extended length of the specimen.

Alternatively, where β is not unity, the correction may be made by using the equation :

$$\log\log\frac{l}{l_0} - \beta\log\frac{l}{l_0} = \beta\log s_0 - \log\psi + k\log t,$$

where s_0 is initial value of stress, and l_0 and l are initial and final lengths of the specimen.

Such correction does not, however, entirely account for the anomalies, and it is suggested that the difference is a fundamental one possibly due to the effect of the inter-molecular forces of attraction and repulsion.

The situation with respect to such factors is very complex and will be affected by the physico-chemical as well as the chemical constitution of the material under test. Thus the shape of the molecules, their orientation, their degree of association and their existence in the form of colloidal micelles will all nfluence the behaviour of the specimen under different types of deformation. General consideration of these inter-molecular forces would lead us to expect a decrease in ψ and k with increasing stress. This decrease is, in fact, found when a single method of est is employed (for example, either extension or compression). That a comparison of results by the wo methods does not fall into this scheme may be due to the fact that in calculating ψ and k certain simplifying assumptions have been made which are not true. In particular, it may be that with these particular materials Poisson's ratio is not 0 : 5 as ad been supposed.

Silica and the Liesegang Phenomenon

The synthesis of a wide range of rhythmic strucures, their relationship to naturally occurring forms nd the physico-chemical basis common to them have ready been studied by one of us (M. C.)[1]. The eliminary experiments outlined in the present note xtend the application of the Liesegang phenomenon silica and its hydrates.

Test-tube experiments with aqueous solutions of mmercial waterglass (1 : 1 by volume) carefully vered with an excess of concentrated hydrochloric cid at about 17° led to the immediate formation of fine network structure which soon became a anslucent membrane at the interface of the two liquids. Within 24 hours, 30 white horizontal bands were formed below the membrane. In the course of the next few days the number of bands had greatly increased—occupying more than 80 per cent of the original column of waterglass. The interband spaces increased as the reaction progressed, the 12 bands per cm. below the membrane gradually being reduced to 9 per cm. at the end of the reaction. On standing, the bands, laminated in structure, tended to arrange themselves in groups.

Experiments with more dilute waterglass (3 volumes of water to 1 of waterglass) led to interesting results. The progress of reaction was accelerated and the bands were found to be more closely packed (15 per cm.), aggregating into groups of about four. Above the membrane, in the region originally occupied by hydrochloric acid, a clear jelly-like mass was found (presumably silicic acid gel) equal in volume to about one third that of the waterglass. In some instances, however, the viscous matter exhibited distinct opalescence. Using concentrated waterglass the reaction is slower, the bands are fewer and thicker, being frequently connected by vertical columns of sodium chloride. This is especially the case when hydrogen chloride is the reagent.

In reactions where sulphur dioxide or sulphuric acid had been substituted for hydrochloric acid, certain anomalies were noted, influencing the pattern of depositions. The radial and network structures characterizing the initial stages of membrane- and laminæ-formation were superseded by, or rather modified into, concentric ring forms. With concentrated waterglass the interference to diffusion (probably due to the influence of specific colloid-electrolyte complexes) converted the regular pattern of the laminæ, as viewed from below, into walnut- and pomegranate-like surfaces. These transitions in the pattern development of the laminæ were well demonstrated in beaker and Petri dish experiments, membranes originating in all cases from the periphery of the surface. This dependence of the type of deposition upon the character of the accompanying electrolyte may be of considerable morphological significance.

The fact that the membrane at the interface of the two reacting liquids was at no time distorted by protuberances, particle eruptions or arboreal growth strongly suggests its colloidal character (compare reactions of transitory and permanent colloids as given in earlier publications). Under the experimental conditions used, there was no transition to anhydrous silica, the stratified precipitate remaining in a state of *limited* hydration. The relation of this state to the *unlimited* hydration of silicic acid gel is analogous to that found in the cases of soap curd – soap gel[2] and hydrocalcite – colloidal calcium carbonate[3].

It is intended to use these results as a basis for the synthesis of such minerals as itacolumite (by compression and subsequent dehydration with or without fluxes), opalite, hyalite, etc.

RESEARCH ITEMS

Mammalian Arm Arteries

THE Field Museum of Natural History has published a volume of eleven papers in honour of Wilfred Hudson Osgood (Zool. Ser., 27; 1941). Osgood's name is well known to all workers in that subject as a first-class field naturalist and a sound and critical systematist. He joined the staff of the Museum in 1909, and during his term of office as chief curator of zoology that department has made extraordinary progress. The longest memoir in the volume is that by D. Dwight Davis on "The Arteries of the Forearm in Carnivores". The classical work of Zuckerkandl contains accounts of these vessels in sixteen species, but the present paper involved the dissection of thirty-five specimens carefully chosen so that twenty-five genera are represented. The information thus obtained, with that previously recorded, enables an extensive comparative survey to be made. The vessel pattern of the forearm furnishes evidence of the inter-generic and inter-family relationships, although some allowance has to be made for functional specializations. The most primitive pattern is to be found in the Hyænidæ, although they show certain cursorial adaptations. The Canidæ are also primitive but fundamentally different from the other Arctoidea. More investigation in the Viverridæ is required before definite conclusions can be drawn, but apparently they exhibit the least primitive pattern among the Aleuroidea.

Control of Cabbage Caterpillars

TECHNICAL BULLETIN No. 782 of the U.S. Department of Agriculture deals with the control of cabbage caterpillars by means of insecticides. The authors, W. J. Reid, jun., and collaborators, have carried out a large series of experiments specially designed to deal with outbreaks at the time when the crop is being harvested, when there is no opportunity for the natural removal of spray residues. Their recommendations, it may be added, are specially applicable to conditions in the south. They demonstrate that arsenicals should not be applied at any time on that portion of the plants which is to be marketed or consumed as food. The whole problem, therefore, was to discover satisfactory substitutes that would kill the pests concerned without leaving harmful residues. The insects involved were mainly the cabbage looper (*Autographa brassicæ*), the diamond-back moth (*Plutella maculipennis*) and the small cabbage white (*Pieris rapæ*). Practically all the experiments were made with materials used as dusts. Talc, china clay, sulphur, tobacco dust and lime were used as diluents for the insecticidal substances. It appears that derris dusts gave the most uniform performance, and a mixture containing 0·5–1 per cent of rotenone is sufficiently toxic to the three pests named to be of value as a substitute for arsenicals. All other treatments were relatively ineffective against larvæ of the diamond-back moth. In view of the frequent severe damage by cabbage white butterfly larvæ in Britain the results of these experiments are of importance on both sides of the Atlantic Ocean. The tests were made by means of rotary hand dust guns and in most cases were at the rate of 15–20 pounds per acre—the quantities being determined by weighing the dust guns before and after each application.

Salmon Gill Maggots

WHILE the presence of a parasite on the gills of the salmon was reported in Scotland so far back as 1766, and is well known to fishermen, its life-history has been worked out and recorded for the first time by G. F. Friend (*Trans. Roy. Soc. Edin.*, 60, Pt. 2; 1941). The salmon is notoriously difficult to keep in aquaria and so ordinary laboratory culture methods could only be applied to the development of the egg, and the rest of the life-history of the parasitic copepod, *Salmincola salmonea*, had to be followed by examining a large number of fish over a series of years. The author has added much to previous knowledge: the free-swimming larval stage, the attached male and female larvæ and several early stages of the female and the attached male (a rare form since only six were obtained to 4,000 females). A useful diagram of the life-history shows that infection takes place on or near the spawning bed after the return of the salmon from the sea, and so, *prior to spawning*, 'n fish was infected. The attached parasite can b carried out to sea and hence the subsequent returns o the salmon serve to spread the infection. The parasite, even when present in numbers up to a hundre on an individual fish, does not appear to harm it host directly but the wounds it makes on the gi filaments by stripping patches may provide point of ingress for pathogenic organisms.

Metasomatic Origin of Granophyre

A 500-FT. sill of dolerite occurring at Hangnest i the Cape Province of South Africa exemplifies ver clearly two well-marked features of the thicke Karroo sills: (*a*) very slight crystallization differentiation; and (*b*) marked tendency to react with an mobilize the associated sediments. A petrologica and chemical study of this sill and a discussion o the petrogenetic processes involved have been presented by F. Walker and A. Poldervaart (*Geol. Mag* 429; 1941). Thick bands of sediment were stope up from the floor and down from the roof and s became enclosed, together with numerous xenolith in the magma. The composition of the sediment was such that they easily underwent mobilizatio this being followed by rheomorphic injection int the dolerite, locally with sufficient force to brecciat the contact facies of the sill. Nearer the middle th rheomorphic veins reacted with the partly crystallize dolerite to form a richly micropegmatitic rock. large xenolithic block of siltstone was metasomaticall reconstituted by introductions of soda and sma amounts of the cafemic oxides, with production of granophyric rock of a type which is of widesprea occurrence in the Karroo petrographic provinc The occurrence recalls the transformation of t Caledonian granodiorite of Newry into granophy of Tertiary type at the contacts of the former wi Tertiary gabbro (D. L. Reynolds, *Proc. Geol. Asso* 265; 1937).

Auto-correlation of Meteorological Time Series

A PAPER by T. E. W. Schumann and W. Hofmeyer, entitled "The Problem of Auto-correlati of Meteorological Time Series, illustrated by Examp from South African Stations" was presented at *meeting of the* Royal Meteorological Society held February 18. The main object of the paper was present a number of characteristic values of t auto-correlation coefficient as actually comput from observed series of temperature and pressu For this purpose the temperature and pressu records of some South African stations were selected. In the case of temperatures, it was found that, provided any daily or seasonal fluctuations are first eliminated and the standard deviation is constant, the coefficient of auto-correlation R' has the analytic form $R'=e^{-ky}$, in which k is a constant and y is the time-lag. If, however, there is a marked variation in the standard deviation, such as is nearly always present in hourly values of temperature, R' is a function not only of the time-lag, but also of the actual times marking the beginning and end of the time-lag under consideration. In the case of a series of pressure readings, R' is not a simple exponential function, but may contain one or more damped harmonic terms.

High-Frequency Attenuation

AN improved D.C. substitution method of measuring high-frequency attenuation has been described by H. B. Noyes (*Bell Lab. Rec.*, 20, No. 2, Oct., 1941). In the design of a wire communication system, attenuation data are practically indispensable, and measurements are often made by passing currents of various frequencies over a section of the line, and measuring the input and output with thermocouples, the accuracy obtained depending on the stability and accuracy of the thermocouples. Although this method is satisfactory on long lines, higher accuracy is sometimes needed, particularly when characteristics of short lines are to be determined. The D.C. substitution method has been found to give more precise results on attenuation measurements of this type and has the advantage of using the D.C. value of a resistance as a standard. The accuracy is practically independent of the calibration and stability of the thermocouple, which is used merely to relate the test-line attenuation to a value of an adjustable calibrated resistance in a D.C. circuit. The method requires, however, that either the D.C. and A.C. sensitivities of a thermocouple be identical, or the ratio between the D.C. and A.C. sensitivities of the sending and receiving thermocouples be identical. As a result of this refined technique, insertion losses at frequencies of 12–68 kc. could be determined with a reproducible accuracy or sensitivity of 0·005 db., a much higher precision than has hitherto been attained, contrasting with an error of 0·1–0·2 db. due to thermocouple errors of older methods.

Field Measurements of Insulation

A PAPER on the above subject presented recently by E. A. Burton, J. S. Forrest and T. R. Warren to the Institution of Electrical Engineers deals with the field testing of high-voltage switchgear, busbar and transformer insulation as a means of alleviating insulation failures in service, and describes the apparatus and methods employed by the authors on the Central Electricity Board system. The three main testing techniques, (*a*) measurement of power factor, (*b*) measurement of potential distribution and (*c*) measurement of insulation resistance, are described and practical testing apparatus, designed to make such measurements under the onerous conditions of field use, are described. Three wattmeter types of power-factor measuring apparatus are described, two for 10 kv. tests for bushing sets, and one operating at 50 kv. for tests on busbar systems. Details are given of a bridge specially developed for field testing, and the measurement of potential distribution on bushings in service is discussed, reference being made to an electronic testing set for the measurement of insulation resistance up to 10,000 megohms at 5 kv. The summarized results of more than two thousand tests on installed apparatus are given and special test methods are described to facilitate power-factor measurements on transformer bushings and orifice insulators. Information is also given on the power-factor of oil in service. Methods are suggested of continuously supervising the insulation of important installations in cases where the lower voltage end of the insulators can be isolated from earth, and finally, the merits and demerits of the three main test methods are summarized in order to assist the maintenance engineer in choosing the method or methods best suited to his requirements.

Surface Films of Lupane Derivatives

MANY sterols and triterpenes containing water-attracting groups form stable unimolecular films when spread on water or, in some cases, dilute acid or alkali. Sterols and triterpenes with hydroxyl groups at the extremities of their ring systems form almost incompressible films with limiting areas of 38–42 A.^{2} and 45–50 A.^{2}, respectively. P. Bilham, E. R. H. Jones and R. J. Meakins (*J. Chem. Soc.*, 761; 1941) have made surface-film measurements on a number of derivatives of the triterpene alcohol lupane, for which there is lack of information as to the positions of the hydroxyl and *iso*propenyl groups. The small limiting-area values found, particularly with bisnorlupanic acid and ψ-lupenol, and the large area values found with lupenediol and lupenetriol monoacetate, in conjunction with the chemical data found by Heilbron and others, furnish evidence that in lupeol the *iso*propenyl group is situated at the opposite extremity of the ring from the hydroxyl group. The curves for the pressure-area measurements on the films are shown and discussed in detail in the paper, which records an interesting application of a physico-chemical method in studying the structure of a complicated organic molecule.

Exchange Equilibria

IN a paper dealing with exchange and transfer equilibria in mixtures of solvents, R. W. Kingerley and V. K. La Mer (*J. Amer. Chem. Soc.*, 63, 3256; 1941) point out that, in a solvent consisting of protium oxide (H_2O) and deuterium oxide (D_2O), in a reaction of the type,

$$\tfrac{1}{2}H_2O + KOD(D_2O) + KBr(H_2O) = \tfrac{1}{2}D_2O + KOH(H_2O) + KBr(D_2O),$$

there is a free energy of exchange when potassium hydroxide is converted into potassium deuterate and also a free energy of transfer of potassium hydroxide and potassium bromide from one solvent to the other. The latter process has not always been correctly treated. In many cases the free energy of exchange is of minor importance. The equilibrium process formulated above was determined from analytical measurements of the process

$$\tfrac{1}{2}HgO + \tfrac{1}{2}Hg + \tfrac{1}{2}H_2O + KBr(H_2O) = \tfrac{1}{2}Hg_2Br_2 + KOH(H_2O)$$

in $H_2O - D_2O$ mixtures and was found to compare favourably with the value calculated indirectly. The solubilities of thallous chloride and calcium hydroxide were determined in the two waters and the exchange coefficient of the base measured in a sample of mixed solvent. The ion product constant of deuterium oxide was calculated indirectly as $1{\cdot}54 \times 10^{-15}$ at 25°, in good agreement with $1{\cdot}6 \times 10^{-15}$ reported by Abel, Bratu and Redlich in 1935.

NATIONAL INSTITUTE OF ECONOMIC AND SOCIAL RESEARCH

THE first report of the National Institute of Economic and Social Research, which covers the year 1940–41, includes a brief review of the history of the Institute since its formation in 1938. The original research programme of the Institute, which was largely planned upon the basis of a two-year period, was prepared by special committees of the Institute constituted for the following subjects: (1) statistical studies of the national income and changes in its magnitude and distribution; (2) location of industry and the distribution of the industrial population; (3) British commercial policy and the administration of overseas trade; (4) the organization of the credit and capital markets; (5) short-period economic change; (6) economic and administrative problems of unemployment.

The work of 1940 fell into two sections; first, the continuation or completion of pre-war studies, and secondly, the war-time research programme adopted by the Council in December 1939.

In the first section (the national income) inquiry was continued throughout the year under the direction of Prof. A. L. Bowley, and a paper incorporating part of the work has been published in the *Journal of the Royal Statistical Society*. Studies of the location of industry have continued and a study of the social and economic conditions in the Highlands has been completed but not yet published.

A report on some of the results obtained on the location and concentration of industry has already been published, and although the industrial survey of Bristol was suspended in 1940, the results are to be published shortly. A report on part of the results obtained in the fertility studies in Bristol has also been published in the *Journal of the Royal Statistical Society*.

The first and descriptive part of the study of trade regulations and commercial policy in Great Britain has been completed, and work on the remaining part has been suspended. The manuscript is now in the press. A study of the organization of credit and money markets in London has been completed by Dr. Thomas Balogh and awaits publication.

The development of the war-time research programme in 1940 was hindered by the insufficient supply of research workers. Under this programme, grants have been made for studies of the effect of the War on the credit policy and credit mechanism of the City of London; the effect of war on municipal finance, Coventry; economic adjustment to the War in Birmingham; taxation of war wealth; burden of taxation inquiry; studies in Russian economic problems; inquiry into savings and spending and on the social consequences of evacuation in south-west Scotland as well as of juvenile employment in Manchester and in Glasgow, and a study of National Health Insurance by Prof. H. Levy. The programme also includes studies in exchange control by Dr. Thomas Balogh, and a grant has been made for a study of war-time changes in Bristol purchasing power, an investigation substituted for the continuation of work on the industrial survey which was suspended.

Since the heavy air raids on Great Britain in the autumn of 1940, damage to the Institute's premises necessitated alternative temporary accommodation, and hospitality was offered by the Royal Institute of International Affairs. During 1941, the research staff of the Institute was increased and the scope of its work expanded. The initiation of its series of publications was undertaken and arrangements were made with the Cambridge University Press to publish the Institute's researches. The report also refers to the work of the National Service Committee for Social, Economic and Statistical Research and of the Consultative Conference for the Co-ordination of Research in the Economic and Social Sciences in War-time.

In 1941, the greater number of applications were received from individual research workers and fewer from universities and university colleges. A list of studies in 1941 and of publications in 1940–41 is also included.

WHISTLING METEORS

IN an article on "Whistling Meteors" appearing in the November issue of *Electrotechnics*, Chamanlal and K. Venkataraman, of the research department of All-India Radio, discuss the Doppler effect produced by meteors entering the ionosphere.

During observations carried out on short-wave transmitters near the Delhi centre of All-India Radio, it was observed that in certain circumstances when a receiver was tuned to the carrier wave, weak heterodyne whistles of an unusual type were audible. The whistles appear as a high-pitched note which rapidly descends in pitch down to zero frequency where they apparently disappear, or alternatively fade away before reaching zero frequency. The whistles vary in duration from approximately a fifth of a second to several seconds and occur at random time intervals. They are most frequent in the early hours of the morning and are infrequently heard during the day-time, the early morning whistle sometimes occurring very frequently.

A heterodyne whistle which first appears with an initial beat frequency of, say, 3 kc./sec. and, after rapidly descending in pitch, disappears without reappearing on the other side of the fixed carrier wave can only be explained by the Doppler effect due to interference between the weak carrier wave reaching the receiving centre as a ground wave and a wave returned from a rapidly moving reflecting surface the latter suffering an apparent change in frequency Assuming a beat frequency of 3 kc./sec. and that the observation is made on a carrier frequency o 7 mc./sec., the velocity of the moving reflecting surface is found to be about 64 km./sec. The descending pitch of the heterodyne beat note is the result o the moving reflecting surface being rapidly retarde in velocity, and the beat note will reduce to zer frequency if the velocity of the reflecting surfac becomes zero. If the beat note disappears befor reaching zero, it may be assumed that reflectio from the surface has ceased before it has necessaril reached zero velocity.

A consideration of this particular manifestatio of the Doppler effect shows that if the reflecting surface is moving towards the point of observation th Doppler effect will appear as a heterodyne whistl on the higher frequency side of the ground-wav from the transmitter. This was confirmed on detuning the receiver slightly from the carrier frequency position. The Doppler effect from a recedin reflecting surface produces a heterodyne whistle on the lower frequency side of the carrier wave.

The only known phenomenon with which sufficiently high velocities are associated and which could cause a Doppler effect of this nature is a meteor entering the earth's upper atmosphere, and confirmation of this was obtained by observations in the early morning hours when the appearance of meteors in the sky coincided with the heterodyne whistle produced in a receiver. The article discusses briefly the number, size, height, and velocity of meteors, the mode of dissipation of meteor energy, and meteor ionization, remarking that the summary provided of some of the known properties of meteors gives ample confirmation of the experimental evidence and deduction that the weak heterodyne whistles observed are due to the Doppler effect caused by the rapidly moving ionized area produced by a meteor. It is evident that, (a) the ionization produced by meteors can be sufficient to reflect waves of the frequencies concerned, (b) the number of whistles observed is at a maximum in the early morning when the number and velocity of meteors entering the earth's atmosphere is greatest, and (c) the velocity of meteors, determined by visual means, is of the same order as that calculated from the Doppler effect observed.

The article concludes with descriptions of the experimental procedure adopted and the results obtained.

NEW DESCRIPTIONS OF SOME INDIAN PLANTS

SOME interesting botanical notes have recently been given by Dr. N. L. Bor, forest botanist, Forest Research Institute, Dehra Dun (*Indian For. Rec.*, Botany, 2, Nos. 2, 3 and 4; Govt. of India Press, Delhi, 1941).

In No. 2 the bamboo *Thyrsostachys Oliveri* Gamble s dealt with. This species, the author writes, owered in the Katha district, Upper Burma, in 1891. pecimens were sent by J. W. Oliver, conservator of forests, to the late Mr. Gamble, who pubshed a description under the above name in the *nnals of the Royal Botanic Garden*, Calcutta, in 1896. eeds of the species were also sent and these were lanted at Dehra Dun in several places, and also in ne Royal Botanic Garden, Calcutta. All those who ave known Dehra Dun during the last forty years ill remember the magnificent clumps of this bamboo. ll the Dehra clumps commenced to flower towards e end of November 1938, the first indication being e fading of the leaves, which soon began to fall off. n the first week of December the flowering shoots, ale purple in colour, were quite evident, and by ecember 12 the lower sheaths of the flowering oots were beginning to show the tip of an emerging ikelet. By December 23 two spikelets had cometely emerged from each sheath, and the six amens, pendulous at the ends of long filaments, ere visible from each of the three florets of the ikelets. Seed was ripe by January 31, 1939. Dr. or says that with fresh material to work upon and limited quantities of it, it became evident that the scription given by Gamble, prepared from dried aterial, required modification in several respects.

A lapse of twenty-four hours is quite sufficient for e features of the structure of the delicate palea to be lost, and no amount of boiling will restore them. This fresh material enabled a revised description to be drawn up which corrects some minor inaccuracies in Gamble's description. Two plates portray the details of the inflorescence and spikelets. This reads like a botanical romance, and foresters in Burma and botanists are likely to be equally interested.

For No. 3, Dr. Bor redescribes Dunn's *Vatica Shingkeng*, placing it in the genus Hopea. The original description was based on incomplete material, especially the flowers. I. H. Burkill, who accompanied the expedition into the Arbor Hills of Assam in 1911, discovered the species. He notes: "no general flowering took place during the expedition, and it was with great difficulty that one flowering tree was found". This flowering specimen was not, however, sent to Dunn, who notes in his description "*flores ignoti*".

In No. 4, Dr. Bor describes three flowering plants new to science: *Gleditsia assamica* Bor, *Garnotia puchiparensis* Bor and *Strobilanthes andamensis* Bor. Illustrations are given of each species. Dr. Bor had collected the Gleditsia in the Aga and Naga Hills and Sadiya in Assam without flowers or fruit. He received these collected in Sadiya in March 1938. It is a small deciduous tree about 10 metres in height.

The Garnotia is a grass and was found growing thickly in the clefts of a large rock just west of the Puchipara rest house, Silent Valley, Madras (alt. 3,000 ft.).

The Strobilanthes is a wiry shrub up to 60 cm. tall, gregarious in habit. The species was collected in flower by the sylviculturist of the Dehra Institute during a visit to the Andamans. It was noted that "the species was abundant in regeneration areas on limestone rocks, growing in crowded bushes 1′–2′ high".

DRUG CONTROL IN INDIA

THE problem of drug standardization and drug control in a country of the size and population of India is a vast one. In Great Britain, the United States and other progressive countries a general consciousness of the evils of food and drug adulteration on community health and national well-being was aroused nearly fifty years ago, and the authorities took up the responsibility of safeguarding public health and money by instituting adequate control of the spurious drug trade. In India, on the other hand, although the possible injurious effects of the adulteration of foods were recognized early enough, the seriousness of the situation arising out of the indiscriminate adulteration of drugs and chemicals for the treatment of diseases received comparatively little attention, and India came to be considered the dumping ground of all kinds of substandard, misbranded and poor-quality drugs and pharmaceuticals.

Realizing the need for both legislative and executive action the Drugs Enquiry Committee 1930–31, appointed by the Government of India, recommended that All-India legislation should be passed for the control of the importation, manufacture, sale and distribution of adulterated and under-strength drugs, and that machinery should be established for the regular collection and testing of drugs to ensure conformity to proper standards of purity and strength. It was suggested that for the standardization of drugs a well-equipped central laboratory should be set up with a competent staff of experts in various branches and that this should be supplemented with provincial laboratories working under the guidance of, and in close liaison with, the central laboratory.

In January 1937 the nucleus of a central laboratory (Biochemical Standardization Laboratory) was established, under the direction of Sir R. N. Chopra, in Calcutta, at the All-India Institute of Hygiene and Public Health. The Laboratory has now made satisfactory progress in the limited number of studies undertaken and has trained adequate personnel and laid sure foundations for future work in this field as evidenced in the triennial report (Report of the Biochemical Standardization Laboratory 1937–40. Government of India Press, Calcutta, pp. 92). During the three years preceding the introduction of the Drugs Bill in February 1940 it was thought that the best course for the Laboratory was to undertake a general survey of the quality of medical drugs in the Indian market and an examination of the specimens of drugs both imported and manufactured in India which were suspected to be of inferior quality.

Many drug manufacturing firms in India do not maintain properly equipped pharmacological laboratories with trained personnel capable of undertaking the standardization of chemotherapeutic preparations, and it was natural that ethical manufacturing concerns interested in the quality of their products should approach the only Government organization available with requests to have their products standardized.

In the initial stages the Laboratory had necessarily to restrict itself to certain definite drugs of comparatively greater importance to the pharmaceutical and medical professions. Routine analytical work was therefore largely concentrated on surveying the quality of tinctures of digitalis, strophanthus and squills, extract of posterior pituitary gland and adrenaline hydrochloride solution. In addition to the routine activities a good deal of interest in research problems on subjects which have a direct or indirect bearing on drug work was consistently maintained. For example, one of the first group of drugs which the laboratory investigated was the cardiac drugs of the digitalis series. Liquid preparations of these drugs deteriorate at a fairly rapid rate when stored under the climatic conditions existing in India, and factors leading to this deterioration and loss of potency have been the subject of investigation. Again, the estimation of the antidiuretic potency of pituitary extract in rats was given an extensive trial and found to be quite reliable and to compare favourably with the results obtained by the oxytocic method. In addition, the Laboratory has the responsibility of acting as the national centre for the maintenance and distribution of certain international biological standards.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public)

Monday, April 13

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5 p.m.—Discussion opened by Colonel Sir Charles Arden-Close, F.R.S.: "The Map of the Pacific".

Society of Chemical Industry (Joint Meeting of the Yorkshire Section and the Food Group) (at the Hotel Metropole, Leeds). Subject: "Colours in Foods". 3 p.m.—Mr. D. J. T. Bagnall: "Comments on Coloured Foods". 3.45 p.m.—Prof. J. W. Cook, F.R.S.: "Physiological Aspects". 5.15 p.m.—Dr. D. A. Harper and Mr. N. Strafford: "The Rapid Spectrographic Determination of Minute Amounts of Arsenic, Lead, Copper, and other Heavy Metals in Food-Stuffs Colours and Medicinals".

Tuesday, April 14

Chadwick Public Lecture (at the Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Mr. D. C. Graham: "Dangers from Rainfall in Urban Areas; Prevention of Flooding of Buildings and of its Insanitary Consequences" (Bossom Gift Lecture).*

Society of Chemical Industry (Chemical Engineering Group) (Joint Meeting with the Institution of Chemical Engineers) (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Discussion on "The Development of New Chemical Processes" to be opened by Mr. H. W. Cremer.

Illuminating Engineering Society (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 5 p.m.—Mr. J. N. Aldington: "Fluorescent Light Sources and their Applications".

Wednesday, April 15

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. J. C. Dawes: "Making Use of Waste Products".

Society of Glass Technology (at Elmfield, Northumberland Road, Sheffield 10), at 2 p.m.—Annual General Meeting.

Institute of Chemistry (London and South Eastern Counties Section) (at 30 Russell Square, London, W.C.1), at 6 p.m.—Dr. Hugh Nicol: "What the Plant does with its Materials".

Thursday, April 16

Town and Country Planning Association (in the Dome Lounge Dickins and Jones, 224 Regent Street, London, W.1), at 1.20 p.m.—"Planning for the Family".

Chemical Society (at the Royal Institution, Albemarle Street London, W.1), at 4.30 p.m.—The Rt. Hon. Lord Rayleigh, F.R.S. Sir Joseph J. Thomson Memorial Lecture.

Friday, April 17

Association of Applied Biologists (at the London School o Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), a 11 a.m.—Symposium on the Pathology of the Hop (Speakers: D W. Ware, Dr. W. G. Keyworth, Dr. A. M. Massee). 2 p.m.—Discussio on the Interpretation of Toxicity Data. (Speakers: Dr. H. Martir Mr. A. F. P. Parker Rhodes, Dr. C. Potter, Mr. D. J. Finney.)

APPOINTMENTS VACANT

Applications are invited for the following appointments on c before the dates mentioned:

Lecturer in the Department of Mathematics—The Registra University College of Swansea, Singleton Park, Swansea (April 22

Head of the Engineering Department and Vice-Principal o the West Hartlepool Technical College—The Chief Educatic Officer, Education Offices, Park Road, West Hartlepool (endorse 'T.C.') (April 25).

Lecturer in Biochemistry in the Department of Physiolog —The Secretary, The University, Edmund Street, Birmingham (April 25).

Assistant Physicist in the Physics Department of the Radi therapeutic Research Unit of the Medical Research Council—Th Director, Radiotherapeutic Research Unit, Hammersmith Hospita London, W.12 (April 27).

Skilled Workshop Instructor familiar with modern machi tool practice, at the Medway Technical College, Senior Department Gillingham—The District Education Officer, Fort Pitt House, Ne Road, Rochester.

Female Assistant Physicists—The Ministry of Labour ar National Service, Appointments Department, Section B/E, Sardin Street, London, W.C.2 (quoting B673E).

Female Assistant Chemists—The Ministry of Labour and Nation Service, Appointments Department, Section B/E, Sardinia Stre London, W.C.2 (quoting B667E).

RECONSTRUCTION AND THE BUILDING INDUSTRY

NOW that building for war has reached, if not passed, its peak, while the demand for man-power and woman-power is still increasing, it is imperative that an attempt should be made to face the post-war problems if physical reconstruction is to be possible on anything like an adequate scale when hostilities cease. The Central Council for Works and Buildings has already issued a valuable memorandum on "Training and Recruitment for the Building Industry", prepared by Mr. G. D. H. Cole for the Ministry on behalf of the Nuffield College Social Reconstruction Survey. Further, at a time when there is some public uneasiness at the delay in the Prime Minister's promised statement on reconstruction and over the supercession of Lord Reith and Mr. Greenwood, the Ministry of Works has issued a statement on the newly created Directorate of Post-war Building. The statement is reassuring evidence that, in one part of the field, preparation is being made to deal with problems which will become urgent immediately hostilities cease and which are indeed linked intimately with the question of demobilization.

The Directorate of Post-war Building consists of a small skeleton staff of fourteen people, but the statement indicates that it has fully grasped the significance of co-ordinating and unifying the many scattered activities of groups and committees in this field and giving them some coherence and direction, if at the appropriate time contraction is to be turned into rapid expansion and orderly and efficient advance. Its first task is that of collating existing information and co-ordinating all activities pursued elsewhere. Its field embraces the whole technical side of building and will include the planning and design of the many types of buildings; the latest practices in construction; the architectural use of materials (and particularly of the newer materials); the most efficient methods for heating, ventilating, lighting and sound-proofing a building, and generally giving it all the advantages that modern science and production technique have put within the reach of man.

The work will be done through groups or committees, most of which are actually or potentially in existence. Where necessary, new study committees may be created at the invitation of the Ministry, either by Government departments, professional organizations, research associations or other suitable organizations. Only in exceptionable circumstances will the Ministry itself convene a committee. Fifteen such study committees have now been discussed in detail or agreed; eleven have been or are being formed and several are at work. The Minister has already provided for co-ordination and policy through a main co-ordinating and three policy committees. All the major interests affected are represented on the main co-ordinating committee, including the Ministry of Health, the Royal Institute of British Architects, the Institution of Civil Engineers, the Department of Scientific and Industrial Research, and the British Standards Institution.

The three policy committees between them cover all subjects for which study committees have been appointed, and consist mainly of the chairmen of the relevant study committees. One of these policy committees, of which Sir Giles Scott is chairman, covers design; a second, with Mr. Ralph Freeman as chairman, deals with structure; and a third, under Mr. G. Grey Wornum, with installations or services. Of the six study committees in this group, two are convened by the Building Research Station, one by the Institution of Electrical Engineers, one, on illumination, by the Department of Scientific and Industrial Research; one by the Paint Research Association and one by the Plastics Federation.

It is clear therefore that in this attempt to seize the opportunity of a general overhaul which the almost complete stoppage of the mechanism of civil building affords, the Ministry of Works and Buildings is making full use of scientific research and technical experience. Past experience is being reviewed and new ideas examined and tried out. If all engaged in the industry respond to this call to pool their knowledge now, regardless of narrow individual interests, there should be an immense improvement in the value of buildings in Great Britain after the War, and the Director of Post-war Building, Sir James West, and his three assistant directors, have every right to count on the full support of scientific workers in their important task.

The statement of the Ministry goes far to meet some of the criticisms of the Association of Architects, Surveyors and Technical Assistants in a recent memorandum entitled "War-time Building". The programme already contemplated should at least remedy the inadequate exchange of technical information, as well as the lack of unified control of building work and of contact between office and site, and design and user, to which "War-time Building" points as among the factors leading to delay in building, inefficiency and the hold up in arms production. It should promote the provision of the unified control of the building programme and co-ordination of planning requirements and structural research which are among the main proposals of that report. Further, it should facilitate co-operation between technicians, which is one of the immediate steps proposed for professional action.

The great problem of the expansion or adaptation of the building industry is, however, the labour question. This may be described as both qualitative and quantitative. The first aspect involves the proper utilization of the technical or scientific worker, upon which the Association of Architects, Surveyors and Technical Assistants lays particular stress. The second is the main theme of Mr. Cole's memorandum, and both are discussed in a recent P E P broadsheet "Building for the Nation".

The Association of Architects, Surveyors and Technical Assistants maintains that insufficient responsibility is delegated to the technical worker, that initiative is discouraged, supervision inadequate and that the organization of technical workers is defective. Together with the lack of unified control of building work, the inequitable allocation of staff, mistakes in placing technical workers and the placing of unqualified persons in responsible posts, as well as the factors already mentioned, it is urged that these defects in organization are leading to considerable waste and inefficiency in war-time. The proposal for full recognition of the status of the technical worker is substantiated by the P E P broadsheet, and also by reports of the Select Committee on National Expenditure.

There is indeed little reason to doubt that the weaknesses which are at the root of the building industry's troubles to-day are due to failure to define responsibilities, to prevent overlapping of functions and to co-ordinate specialized activities. *Planning* lays down the basic principle that the responsibility for design and for co-ordination of services involved in the preparation of plans and other documents for subsequent general supervision should rest upon the architect or engineer. Responsibility for measurement services—quantities and costs—on the basis of the particulars provided, should, in accordance with the proposals of the Association of Architects, Surveyors and Technical Assistants, be placed entirely on the quantity surveyor. Responsibility for co-ordinating work in progress should be clearly defined, and if it remains a responsibility of the architect, co-ordination must be provided much more efficiently than is possible at the clerk of work's or general foreman's level. *Planning* visualizes three ways of providing the threefold service of co-ordination, design and measurement: by the architect and individual specialists; by groups of architects; and by an inter-professional group. The suitability of these types of professional organization will depend upon the scale and complexity of the work in hand. Responsibility and payment for design, measurement and professional co-ordination services should be kept completely distinct from the provision of building materials and from contracting and sub-contracting work. Further, salaries offered to technicians in public services should compare favourably with those offered for similar work in private employment in order to make it possible to enlist the best brains available. Further scope should be provided for the recruitment of a proportion of senior officials at a more mature age after varied experience of normal private, industrial and professional conditions.

The co-ordination achieved through this reorganization of design and measurement services should be directed to ensure proper particulars as the basis of building policy and of national standards of cost control. The organization of the services of contractors calls for a similar critical analysis, and it is highly desirable that the services of the building contractor should be governed by professional standards comparable with those of the architect, the surveyor and the engineer. The absence of any definite pattern of professional relationship throughout the building industry and the dearth of technical administrators from which building organization is suffering, particularly in the Government service, find pointed comment in the P E P broadsheet, which also emphasizes the vital necessity of greatly extending the existing Government research stations both in scope and in size to meet the demands likely to arise after the War. Scientific research, statistical investigation and information services should be vigorously developed to bridge the gap between building research and practice, to stimulate attitudes of self-criticism and to accelerate the adoption of up-to-date methods.

The broadsheet lays particular stress upon the great responsibility of the recently created National Council of Building, although it concentrates its attention on a few of the vitally important aspects of the industry, particularly the long-term policies, including education both at the professional and the operative level. The importance of protecting the consumer, particularly by means of scientific research, and the desirability of exorcising haste from building policy, thereby ensuring speed, and the opportunity which the Government now has as the sole building owner in war-time of improving the efficiency of the industry, are other points stressed in this admirable survey.

The quantitative aspects of the labour problem are also visualized. The new forms of organization to be developed are one means of achieving the best output with the minimum of man-power, and the new status for contractors and the improvement of professional standards generally should have as counterpart a new status for labour. This implies the development of trade unions themselves more on the lines of professional bodies, concerning themselves more with education and the ability of their entrants, and with their opportunities for gaining wider qualifications—for example, by training schemes and a more constructive approach to apprenticeship.

Real developments in this field depend upon effective permanent measures to abolish under-employment and to secure to the workers the sure prospect of a steady load on the industry through large-scale planning. It is to this aspect that Mr. G. D. H. Cole's "Memorandum on Training and Recruitment for the Building Industry" directs special attention. The possibility of bringing about without friction an expansion of the labour force of the building industry on the scale required for post-war reconstruction depends, Mr. Cole concludes, on the giving of adequate assurances that building activity will be maintained at a high level over a considerable period of years. The prolonged depression in the industry before 1914 had disastrous consequences both in checking the flow of apprentices into the building crafts and in causing, in the period after 1918, a deep-seated fear that the acceptance of any schemes for dilution or the recruitment of additional workers would only mean heavy unemployment in the years to come. The building workers were not induced to co-operate readily in schemes of expansion until in 1924 Mr. Wheatley gave guarantees of a continuous programme of building at a high level, and thereafter the great trade depression of 1931 dealt a fresh blow to confidence.

Mr. Cole points out that the building worker needs to be satisfied on two points. He wants an assurance that any building policy requiring an influx of additional labour will be maintained for a substantial period; and he wants also, particularly if he belongs to one of the outdoor trades, a guarantee that his earnings will not be seriously affected by loss of time owing to bad weather conditions. These two requirements are not unreasonable. They are in keeping with the four freedoms of President Roosevelt and with the terms of the Atlantic Charter, and should be met as a preliminary to the introduction of ambitious programmes for the expansion of the supply of building labour.

While, as Mr. Cole's inquiry shows, it is quite impossible, apart from considerations of policy, to make any prediction about the total demand for building labour after the War, that very dependence upon policy, both in relation to housing and in relation to industrial and other non-residential building, should facilitate rather than hinder the giving to the industry of a guarantee of employment at a high level for a period of at least ten years. Obviously it is desirable to plan for the physical reconstruction of Great Britain over a considerable number of years, beginning mainly with the repair of damage by bombs and the arrears of repairs and maintenance, and thereafter proceeding to large schemes of urban re-planning and rural development which will involve the complete rebuilding of many congested areas, as well as substantial changes in the location of industry and population. Here Sir John Orr's plan for a 'temporary' housing scheme might be considered. Mr. Cole enumerates fourteen major points of policy requiring decision before any prediction can be made as to the size to which the building industry must be expanded after the War, but he assumes that the basic problem will be that of getting into the industry as many skilled, or fairly skilled, workers as can be made available by extensive measures of training, and that the actual volume of post-war building activity will depend at least as much on the success achieved in expanding the skilled labour force as on any other factor.

The 'wet time' problem should be solved by means of a guaranteed week, financed at least in part by some sort of pool to spread the cost over industry as a whole. Reassurance on these two points, Mr. Cole considers, would ensure trade union co-operation in bringing about the expansion of the industry on the required scale. Any public formulation of post-war policy for the expansion of labour supply should begin with plain declarations on these two questions. The rebuilding of Great Britain should be planned in advance as a process to be spread over a period of years, divided into successive stages; and the 'wet time' question should be tackled simultaneously by the grant in some form of the guaranteed week.

If this be done, the trade unions of the building industry can be safely asked to waive, for the time being, any regulations which seriously restrict the number of apprentices, either for a particular firm or for a whole district, and also to co-operate closely in bringing into the industry an additional supply of skilled labour. Mr. Cole's proposals include working out in advance a scheme for the completion of interrupted apprenticeships, as well as of a national apprenticeship scheme for the various building crafts.

Mr. Cole recognizes the importance of making the fullest possible use of the available technical colleges and other technical institutions, of expanding the facilities for institutional training in the building crafts and professions, and of providing for vocational specialization in building and kindred techniques in both secondary and part-time continuation schools. The possibilities of the junior technical schools, which offer boys of thirteen a three-year course of secondary education with a strong vocational background, have already been emphasized in a preliminary report by the Education Committee of the Central Council for Works and Buildings. The fresh outlook which Mr. Cole brings to the problem in his comprehensive analysis is, however, particularly well illustrated in his proposal that the training of 'handymen' working for small repairing and decorating firms should be recognized by the industry as a problem requiring special action. Such recognition would in effect mean recognizing a new craft, but Mr. Cole urges that definite provision should be made for training workers of this type.

Here as elsewhere, the post-war policy of expansion may involve considerable modifications of the existing rules of demarcation between crafts. The use of the new materials means training in new crafts and processes, and a new and wider outlook on the part of the trade unions as well as of management and professional men. We cannot expect that outlook and the full co-operation essential to success unless, as Mr. Cole insists, we tackle first the problem of social security and, by eliminating the fear of unemployment, bring a new spirit into the industry. This point was stressed by Lord Portal, the new Minister of Works and Buildings, in an address on April 8 to the National Federation of Building Trades Employers, discussing the importance of organization for immediate activity on the close of hostilities, when he stressed the need for ensuring continuous work for the operatives of the industry.

The dominant note of these surveys is one of opportunity. There are many problems of organization to be solved, questions of professional training, of education and research, if we are to realize the possibilities which the new materials have put into our hands, as the Director of the Building Centre, Mr. F. R. Yerbury, showed in a recent paper before the Royal Society of Arts, on the adaptation of design to standardization and mass production. The statement of the Ministry of Works and Buildings shows that the Ministry is fully alive to the opportunities which lie before it. The most important step, however, remains that of creating the right outlook and inspiring the right spirit from top to bottom of the industry. For this reason the Ministry could give no firmer assurance of its determination to discharge its responsibilities than by dealing with this question of social security. Action in that respect now would fortify and intensify the whole national purpose and effort by giving an earnest of the Government's determination to see that the new order to be established after the War will be worthy of the sacrifices now demanded of every man and woman.

PHILOSOPHY AND THE SCIENCES

Hippocratic Medicine: its Spirit and Method

By William Arthur Heidel. Pp. xvii+149. (New York: Columbia University Press; London: Oxford University Press, 1941.) 13*s*. 6*d*. net.

THE exact relationship of philosophy to the sciences has long been a much-debated subject, although there is to-day general agreement among the writers on ancient thought. The older generations of historians tended to regard the earliest philosophy as similar to modern science in object and method, although they admitted, or rather assumed, its strongly metaphysical character. Recently, however, efforts have been made to prove that Greek philosophy was entirely different from modern science. It did not aim, it is contended, at increasing man's control of Nature, but at satisfying his religious instinct; the method adopted was not induction, with observation, experiment and verification, but dogmatic assertion of rational but unverified—sometimes unverifiable—hypotheses. In other words, it was a theology based on faith. This was 'philosophy' in its narrow sense. There was a wider, vaguer meaning, according to which it embraced logic, ethics; education and so on, if studied in a serious and systematic way, but it bore no resemblance to the physics and chemistry of modern times.

In his book on Hippocratic medicine the late Prof Heidel put forward the theory that, besides being philosophers, early Greek thinkers were also scientists who tried to classify and explain phenomena and sense-perceptions. His evidence is practically limited to the sphere of medicine, but the seventy works of the Hippocratic "Corpus", written between 450 and 350 B.C., afford plenty of material. While fully realizing their faults, Heidel believes that the writers of these works were scientific (in the modern sense in (1) their general conceptions, for example, that the nature of man cannot be understood apart from universal Nature of which man is a part; and in (2) their practice of using scientifically the few means and instruments available in their day. In other words they had the scientific attitude of mind. Their chief faults were that they were dogmatic and speculative regarding as simple what was really complex.

Without these medical works, says Heidel (p. 18) the fragments of the philosophers are scarcely intel gible. For the influence of Plato and Aristotle—particularly of Plato—was so great that the stress they laid upon a narrow metaphysic has obscured th whole history of thought, casting into oblivion nearly all the evidence for the development of Greek science The medical treatises alone have survived, havin been saved by their practical utility.

Such is the theme of Heidel's book. It has it faults; the author, for example, failed to appreciat the unique character of Greek metaphysics, makin rather strange statements about the early philosophers. Nevertheless, if the main contention be correct, much of the history of philosophy must b re-written, and our conception of Greek though freed from the metaphysical bias due to the outstanding genius of Plato. Heidel knew the Hippocratic treatises through and through, expounding the views and explaining their attitude with accurac and thoroughness. All future historians of Greek thought must regard these medical works as primar authorities, instead of using fragments of them as is the modern practice, as secondary authorities to reinforce conclusions based on very different material. As evidence for the development of thought they are as valuable, or almost as valuable, as Plato and Aristotle. W. H. S. JONES.

AN INTRODUCTION TO METEOROLOGY

Introduction to Meteorology

By Prof. Sverre Petterssen. Pp. ix+236. (New York and London: McGraw-Hill Book Co., Inc., 1941.) 17*s.* 6*d.*

THE author of this book is immediately faced by the problem of deciding how much knowledge of mathematics and physics he can assume his reader to possess, since meteorology is concerned with the physics and dynamics of the atmosphere. Dr. Petterssen has assumed that his reader has a knowledge of the elements of the differential calculus, and of rather more than the rudiments of the theory of heat. On this basis he has written a book which can certainly be added to the relatively short list of good books on the subject of meteorology. The general bias of the book is implicitly in the direction of applications to aviation.

Of the fifteen chapters into which the book is divided, Chapters 8–13 are directly concerned with the synoptic chart and its use, and the first seven chapters have been written with the aim of supplying the theoretical ideas underlying the use of synoptic charts for weather forecasting. The earlier chapters cover the consideration of evaporation and condensation, adiabatic changes, stability and instability, temperature changes and their relation to weather phenomena, and wind systems. These are all discussed rather briefly, but on the whole very clearly. The present reviewer was particularly impressed by those portions of the book which are devoted to types of precipitation, types and modes of formation of fog, the genesis of air masses, weather analysis and the steps in forecasting procedure, and the detailed discussion of examples of charts for western Europe and the eastern Atlantic. The parts of the book which deal with synoptic charts are, as might be expected from one who has taken an active part in the development of the Norwegian methods of forecasting, clear and full of matter of great interest to the student of weather forecasting.

The author's view of what constitutes an elementary treatment of meteorology does not accord with the popular view. His book will demand close attention on the part of the reader, as it is very much concentrated. It would probably have been beneficial, from the reader's point of view, to have amplified portions of the earlier chapters. For example, where the formula for the dry adiabatic lapse-rate is expressed as g/c_p, on p. 52, it is not explained that the specific heat at constant pressure is to be expressed in dynamical units, though the elementary reader would probably think of this quantity as expressed in heat units. The actual values of the constants used in the formulæ are not given, and it would be helpful to the reader to have these constants collected into a table, so that if required their values could be readily ascertained. The numerical value of the dry adiabatic lapse-rate is given, on p. 53, as 5·6° F. per 1,000 ft., instead of 5·4° F. per 1,000 ft., the value which the formula yields.

The last two chapters give Köppen's classification of the climates of the world, and a brief historical review of the development of meteorology as a science. Dr. Petterssen concludes his book with an optimistic view of the future of weather forecasting, but whether that view will be justified or not, it is safe to forecast that the book under review will have its part in the spread of knowledge of modern meteorological methods. D. BRUNT.

ENGINEERING DATA

The Engineer's Year-Book of Formulæ, etc.

Originally compiled by H. R. Kempe and W. Hanneford-Smith. 48th annual issue, revised under the direction of L. St. L. Pendred. Pp. xii+2852. (London: Morgan Brothers (Publishers), Ltd., 1942.) 35*s.* net.

SHOULD some future historian wish to write of engineering in 1942, he will find most, if not all, of the important facts in "Kempe". Practically every branch of engineering is represented, as the full title shows, the only notable absentee from the list being chemical engineering which, on the purely engineering side, may be said to derive from certain aspects of other sections—civil, mechanical, electrical and metallurgical—while on the chemical side it belongs to another branch of technology.

The present edition marks the occasion of the quinquennial revision, which is made the opportunity for a thorough overhaul of each of the forty-seven sections in which the information is presented. Obviously, of course, the great bulk of the book remains very largely as before, for much of it is fundamental and almost permanent, and the rest has been carefully selected and tested in previous years. The mining section is one of those that have undergone major treatment and the work of the late Dr. Henry Louis has been revised, considerably extended and brought up to date by Sir Richard Redmayne, whose authority in the world of mining gives assurance that this section is now fully in line with the most recent knowledge and standards.

Other sections which have received similar treatment include those on steam, hydraulics and hydraulic transmission of power, marine oil engines and aero engines. As a result, "Kempe" is not only a larger volume but also has made a definite advance in conformity with the manifold activities of the great body of engineers.

Besides the practical information relating to these numerous aspects of engineering operations and design, the earlier sections are devoted to the more fundamental data which are in constant demand both by the student and by the practising engineer. These include units of measurement and equivalents, the principles of mechanics, measurement of power, heat, optics, acoustics, vibration, noise, the properties of engineering materials and metering and mechanical testing appliances. Then again, in the building section, there is given an abstract of the provisions of the London Building Act, which for some time to come will be the principal guide to conventional and approved practice. By its comprehensive inclusion of engineering information, "Kempe" is equal for purposes of reference to quite an extensive library, and the information is more accessible and more easily applied.

Physical Chemistry for Colleges

A Course of Instruction based upon the Fundamental Laws of Chemistry. By Prof. E. B. Millard. (International Chemical Series.) Fifth edition. Pp. ix+600. (New York and London: McGraw-Hill Book Co., Inc., 1941.) 26*s*.

PROF. MILLARD'S book has now reached its fifth edition. Like many American text-books of science it is excellently printed and bound, but its price is notably greater than that of British books which are of a similar scope.

The treatment follows the usual lines so far as the older 'classical' physical chemistry is concerned, but is noteworthy for the care which has been taken to provide many tables of experimental data and accurate modern values of experimentally determined constants. These are used as the basis for an unusually large number of numerical exercises which are appended to each chapter. Discussions of the states of matter, of the properties of solutions and of thermochemistry and thermodynamics are clearly written and copiously illustrated. The discussion of kinetics is confined to the treatment of homogeneous reactions.

The least satisfactory chapters deal with more modern work, and the discussion of atomic structure does not seem to have been rewritten since the book was first published in 1921. It gives a brief account of the Lewis cubical atom and of the Bohr theory of the hydrogen atom, but does not include even a description of the general Bohr theory of extranuclear structure and the periodic law which is now so fundamental for chemistry. This omission should be rectified in any future editions. S. S.

Practical Physics

By the Physics Supervisory Staff, Engineering Science and Management Defense Training, under the direction of the Division of Arts and Science Extension, the Pennsylvania State College. (Foundations of Engineering.) Pp. viii+165. (State College, Pa.: Pennsylvania State College, 1941.) n.p.

THIS course is designed for a very specific purpose, namely, to furnish training in the fundamentals of physics for workers in the defence industries of the United States. The scope of the work includes the usual subjects, with the exception of sound and light, of a standard roughly equivalent to the School Certificate in England and Wales; in some cases the standard is slightly higher.

The first chapter deals quite adequately with fundamental units and their measurements, and this chapter is typical of the thorough manner in which the work of the whole book has been done; each chapter is practically a self-contained unit. The general plan throughout the book seems to be to deal with the theory first, follow this up with a useful summary and a comprehensive set of questions, and then deal with the experimental work. In the examples, emphasis is placed on the practical and industrial applications of the principles studied. Many diagrams are given, but several of these are in lighter vein and could easily be omitted.

Much has been attempted in the book, and much accomplished, and one feels that the students for whom the book is intended should derive great benefit from its use. The authors are to be congratulated on their enterprising and sound piece of work.

Elementary General Science

Edited by J. M. Harrison. Book 3. Pp. vii+247. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1941.) 5*s*.

THIS rather high-priced book completes a course in elementary science from which it is suggested that schools select subject-matter to suit their own particular needs. The earlier chapters are arranged so as to interlink the various sciences so far as possible, while the remaining chapters deal with work necessary to meet the requirements of students taking the general science paper in the School Certificate Examination. One distinct asset of the book is the good sectional diagrams which are made as simple as possible so that students can very easily follow them; the diagrams of microscopes and telescopes are particularly good. It must be distracting to students, however, not to find diagrams on the same page as the corresponding descriptive matter; examples of this occur on pages 167 and 169.

Certain omissions, which one feels ought to be remedied, are noticeable. For example, in dealing with the mechanical equivalent of heat, Joule's pioneer work is quite rightly stressed, but a more modern method of determining this important relationship would have been welcome. There is a good selection of questions at the end of the book, though no answers are given to the numerical problems.

Experimental Physical Chemistry

By Dr. W. G. Palmer. Pp. xii+322. (Cambridge: At the University Press, 1941.) 12*s*. 6*d*. net.

DR. PALMER'S new volume is noteworthy for the simplicity of the apparatus used to demonstrate fundamental laws and for the very detailed instructions which are given for carrying out the experiments. Each chapter is prefaced by a condensed account of the relevant theory; this is done so that (to quote from the preface) "the student can readily refer to principles while at work on a problem".

This is a very desirable aim but it is doubtful whether the highly compressed and sometimes inadequate notes on the theory will really help the more earnest student. Dr. Palmer's book will chiefly be valued for the many practical dodges which are described for the construction of home-made apparatus. S. S.

Practical Physical Chemistry

By Prof. Alexander Findlay. Seventh edition, revised and enlarged. Pp. x+335. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1941.) 12*s*. 6*d*. net.

PROF. FINDLAY'S book has now reached its seventh edition; it was first published in 1906 and the last impression of the sixth edition appeared in 1938. The new edition is enlarged by the inclusion of descriptions of modern equipment for thermostats and, *inter alia*, some additions to the sections on surface tension, electromotive force, and binary and ternary equilibria.

The author has wisely resisted the temptation to enlarge the book considerably by the inclusion of many new and specialized topics. After more than three decades of useful life it remains an excellent and inexpensive guide to practical work in physical chemistry. S. S.

A Review of Driers and Drying

By E. F. Bennett. Pp. 90. (London: *Paint Technology*, 1940.) 3*s*. 6*d*. net.

DESPITE the age-old use of linseed oil as a medium for protective and decorative finishes, it is only in comparatively recent times that a serious attempt has been made to study the fundamental aspects of the drying phenomenon. In this review on driers and drying the author has attempted to collect and collate the large volume of published work which by now has accumulated in scattered technical journals, and to present a concise and critical survey of the existing knowledge. The entire field bristles with intricacies. The drying oils themselves are complicated mixtures and the transition from the soluble liquid state to the final insoluble solid film is the result of the interplay of complex physical and chemical changes.

Though small in compass, the book is comprehensive in treatment. It covers the constitution of the various oil types, the general principles of the drying phenomenon, the respective roles of oxidation and polymerization in film formation, the influence of metallic driers, film structure, the constitution of varnishes and the influence of pigments. This admirable compilation of the information on drying oils and driers with its 106 references is interesting and valuable from the theoretical point of view and at the same time it offers much practical and useful information for the guidance of the paint technologist.

The book is highly recommended by two acknowledged authorities on the subject, Dr. J. S. Long and Dr. William Krumbhaar, who in extended forewords contribute lucid and suggestive analyses of the problems awaiting solution by research workers in this field.

The Twin Marchant Calculating Machine and its Application to Survey Problems

By Dr. L. J. Comrie. Pp. 40+3 plates. (London: Scientific Computing Service, Ltd., 1942.) 10*s*.

IT would be difficult to exaggerate the importance at the present time of easy and rapid methods of solving the day-to-day mathematical problems that arise in military survey work. A large number of such methods, many developed by Dr. Comrie himself, depended in the past on the use of the German Brunsviga Twin 13*z* calculating machine. The fact that this machine is now, naturally, unobtainable might well have seriously handicapped our fighting forces. It is therefore extremely gratifying to learn that a substitute has been provided by the device of building together in pairs the well-known American Marchant machines. As Dr. Comrie remarks, this improvisation does not produce the ideal twin machine, but at least it gives us a serviceable and urgently needed war weapon.

Dr. Comrie's booklet describes this Twin Marchant and deals in detail with its application to about a dozen of the fundamental problems of survey work. The methods, which make full use of the time- and labour-saving possibilities of the machine, are described clearly step by step. The book assumes no knowledge of calculating machines on the part of the reader, and so eleven of its large pages outline fully the use of the ordinary single-hand calculating machine and many of the tricks which experienced computers use to shorten their labours. These pages will be useful, not only to those who have to deal with survey problems, but also to a very much larger class of computers and particularly to beginners.

S. L.

Elementary Physics and Chemistry: for Students of Biology

By Dr. E. A. Woodall and E. C. Denne. Pp. 224. (London, Bombay and Sydney: George G. Harrap and Co., Ltd., 1941.) 4*s*. 6*d*.

THIS volume is intended as a two-year course to cover the work necessary for students taking biology in the General Schools Examination, the work to be done in the two years preceding the examination year. The chemistry portion is relatively thin, for the authors point out that little subject-matter is required and much of this can be taught in its proper context in the biology course. In the physics portion, on p. 17, the student is told that inertia is a *property*; later he is told that mass is a *quantity* of matter; he will probably be a little fogged when, immediately after this, he reads that "mass and inertia are really the same thing", even though there is a qualifying note. Not everyone will agree that the section on light should start with the spectrum, to be followed by reflexion and refraction, and one wonders why the experimental methods illustrating laws and principles are placed all together towards the ends of the chapters instead of putting them in their proper place in the text.

The diagrams in the book are simple and well done (incidentally Fig. 116 is not quite up to date), and a very useful feature is the use in biology of the principles discussed.

The Story of Electromagnetism

By Sir William Bragg. Pp. 64. (London: G. Bell and Sons, Ltd., 1941.) 1*s*. 6*d*. net.

THIS booklet is a reproduction, with certain modifications, of a lecture given by the late Sir William Bragg to cadets of the A.T.C. in the London area. It must have been a 'red-letter' day in the lives of these youths to have had the privilege of listening to so eminent a personality and one so renowned in the field of science. The purpose of the lecture was to give a sketch of the gradual realization of the fundamental principles of electromagnetism, principles on which a great deal of the future work of the cadets is based. The treatment of these principles is rather unique, and could only have been done in this way by the expert, the master of his subject, as was Sir William Bragg.

In the first chapter the four fundamental principles of electromagnetism are set out, and in subsequent chapters the author follows the course of discovery, observing the events which led up to the recognition of each of the principles. The amount of ground covered in this small book is very extensive, and the book should be studied not only by A.T.C. cadets but also by those who train them and by all students of physics.

Sir William Bragg added here one more notable contribution to the many he rendered to the world of science, and it is characteristic of him that, in his last published book, small though it is, he should have returned to fundamentals, discussing them in his own inimical way chiefly for the enlightenment and stimulation of the younger generation.

RACE AND FASCISM

THE second of the two symposia recently arranged by the Faculty of Science of Marx House (Marx Memorial Library and Workers' School) was held at the London School of Hygiene and Tropical Medicine on Easter Monday, April 6. The session was concerned with "The Scientific Attitude to Fascism with particular reference to Racial Theories", and Dr. C. S. Gibson acted as chairman. Six papers were read. It was understood that the views expressed were not necessarily those of Marx House, and the speakers were united more by a common interest in refuting Fascist ideas than in supporting Marxism.

The three papers read during the morning meeting dealt chiefly with race considered as a biological concept. Prof. J. B. S. Haldane opened with a discussion of "Racial Theories and Biological Fact". His chief concern was in rebutting the Nazi racial theory. This was said to be based on three main propositions: (1) that racial differences are absolute and that they determine cultural differences; (2) that some races are superior to others; and (3) that racial crossing is harmful.

The assertions made under the first head, Prof. Haldane said, are "un-Darwinian and undialectical". Races are nothing fixed: they were formed and evolved through the interaction of isolation and mixture. It is probable that whites and Negroes arose by specialization from brown peoples, and in other instances the existence of populations of intermediate type can be attributed to crossing. That there is no essential correlation between race and culture is demonstrated by the fact that very different races have passed through very similar cultural stages.

In adaptation to climate one race may be supposed superior to another in a particular environment, but there is little evidence for superiority in innate aptitude for civilized life. Many observed differences can be attributed to tradition, diet and, above all, chronic disease. Alleged superiority might be due to higher average performance, or to the greater frequency of gifted individuals. It has not been demonstrated that any race surpasses another in either respect, but even if it had, the overlap found would be too great to justify discrimination against the inferior race. Adequate investigation of these matters would require comparison of large samples under conditions of equality in differing environments.

The third point, regarding the harmfulness of racial crossing, is not substantiated by any genetical evidence. On the contrary, hybrid vigour might be expected in the first generation, though no example of it can be given in man. The mixing of cultures may be as important as that of races, and a hybrid culture may be of great value to humanity.

In conclusion, Prof. Haldane stated that believers in racial superiority commonly believe also in the superiority of their own class within the race, and he stressed the scientific importance of studying the social origins of racial theories as well as the theories themselves.

Dr. G. M. Morant, who followed with a paper on "The Meaning of Race", pointed out first that scientific workers have hitherto failed to reach any general agreement regarding racial problems. They are the special concern of physical anthropologists, who agree to-day in supposing that race is a biological matter which must be judged from body characters and not from cultural evidence. The term is applied to sub-groups of the modern species of man which have to be distinguished in order to discover how the total group evolved. The aim is to construct a pedigree in which the units are populations and the ideal groups may be called races.

The most important conditions involved in defining and classifying races of mankind are: (1) the fact that characters show gradations in conformity with the geographical positions of the populations compared, and (2) the fact that different characters distinguish populations in different ways. It follows from (1) that races can only be defined in an arbitrary way, and there is no agreement yet regarding the conventions and nomenclature which can best be used. Analysis on statistical lines offers the best hope of leading to a satisfactory solution of the complex problem, and this need not conflict with any knowledge regarding heredity in man.

Finally, Dr. Morant pointed out that the biological conception is entirely antagonistic to the view, derived from cultural evidence and used for purposes of national propaganda, according to which races are populations which can be sharply divided from one another.

Dr. P. A. Gorer's contribution dealt with "Disease and Race". He discussed the facts that the incidence of certain diseases varies greatly in different areas and that such differences may exist between different ethnic groups inhabiting the same area. The problem is whether this diversity is genetical in origin or due to other causes.

The case of yellow fever was cited as an example of the difficulty of interpreting the evidence. The high resistance shown by West African Negroes might be attributed solely to genetical factors acquired through natural selection. It is doubtful whether this is entirely true, however, since the disease is much less severe in childhood, so that most of the adults will have been immunized as children. Population differences in the incidence of cancer may be due to environmental rather than genetical factors. Both kinds must be supposed involved in the case of infectious diseases. Knowledge of the etiology of mental differences is less developed, though it is in this field that the most dogmatic assertions regarding racial distinctions are made.

The moral drawn by Dr. Gorer is that appreciation of the difficulties to which he referred should act as a deterrent against hasty deduction from racial differences of other kinds.

Questions asked following these three papers related to 'identical twins', intelligence tests and cancer in Java, among other topics. One speaker raised a current political issue in asserting that an attempt was being made to disrupt India on racial grounds. As a result a resolution was passed unanimously during the afternoon to the effect that: "This meeting . . . deplores any attempt to base political boundaries on alleged racial differences, and in particular the suggestion that the peoples of India should be divided politically on racial grounds".

It cannot be said that the adoption of this motion was an example of the working of a democratic practice at its best. The matter was not discussed, and few people in the audience can have appreciated its implications. Has anyone suggested that India should be partitioned on the basis of race? As Prof. Haldane had pointed out earlier in the morning, it is commonly supposed that there are racial distinctions between castes of Hindus. He and the other speakers had emphasized the point that race is an ill-defined concept, from which it may be inferred that use of the term in concise statements of political significance should be avoided.

The afternoon meeting was opened by Mr. C. F. C. Hawkes, who spoke on "Prehistory and European Civilization". His theme was the group feeling of nationalism. This is always associated with some sort of belief in a distinctive group ancestry, but its main concern is belief in a distinctive cultural inheritance.

Racial theories used as national propaganda aim at intensifying both beliefs by disseminating dogmas regarding a nation's biological and cultural past conjoined. It is alleged that the doctrine is guaranteed by several branches of learning, of which prehistory is one. Racial nationalism declares that there were distinctive 'pure' races in prehistoric times, even if they cannot be found to-day. In fact what prehistory finds is culturally homogeneous groups. Cultural distinction must embody distinctive factors of habitat, economy and social structure, and it cannot be supposed that these are entirely without a biological counterpart. Nationalist race prehistory is not mere fiction but falsification of something real.

Mr. Hawkes then outlined the cultural development of the German region. In neolithic times it received elements of civilization indirectly from the Near East. A homogeneous Bronze Age culture resulted from the fusion of the neolithic people with invaders from the east who had retained the nomad tradition of the steppes. This encouraged the belief that the distinctive German culture was due to a distinctive group ancestry, although in fact the Bronze Age Germans largely migrated during the Iron Age. The tradition of German culture has always been associated with strong group feeling, and it has been peculiarly compact since prehistoric times. Belief in its distinction is deep-rooted, but it might be modified by re-education. Prehistory can play a part here by emphasizing the truth that progress has been conditioned not by racial exclusiveness but by the mingling and interaction of peoples and cultures.

From the questions which were asked regarding the archæology of Europe after Mr. Hawkes's paper, there had evidently been general appreciation of the importance of prehistory in refuting assumptions of the exclusiveness and superiority of Germanic culture. In that way, a study which may appear at first to have no practical applications must be taken into account in examining racial beliefs which are of great practical importance.

Prof. H. Levy dealt with anti-Semitism from the 'materialist' point of view, and he stressed the need for an objective treatment of the topic. Two questions examined were: (1) Why have the Jews survived? and (2) Why does anti-Semitism exist and reach climaxes at different times? Answers depending on the assumption that the Jews cannot be assimilated because they are of a distinctive type, or because they have a divine mission, can obviously be discarded. A proper appreciation of the situation can only be obtained from the history of the people. Their wide dispersion in Europe occurred at a time when the feudal system was in force, and they had no place in it. Consequently they remained without roots in any country. Being 'mobile', they were liable to be used by one party against another at any time of social crisis. The Jews were hence driven inwards and they persisted as a coherent group, clinging to its own traditions. Outbreaks of excessive anti-Semitism have always been associated with national revivals, and the correlation between the two can be traced from the Crusades to modern times. According to Marxist interpretation, a solution of the Jewish problem is essentially linked with a solution of the social problem. Prof. Levy's view is that both have been solved together in the U.S.S.R.

Miss Dona Torr discussed "Race, Nationality and Class" from a Marxist point of view. She was concerned with the political and social concept of race. An outline was given of the way in which historical materialism interprets such questions as the development of national unification and its relation to capitalism, class and international affairs in different historical phases. The social origin of certain racial theories of political significance and the Marxist view regarding the right to national independence were then discussed. In conclusion, she referred to the treatment of 'nationalities' in the U.S.S.R. It was stated that their territorial autonomy is recognized and that their languages and cultures are fostered.

The discussion following the last two papers was concerned with political rather than scientific topics. In winding up the proceedings, Prof. Haldane claimed that this was the first occasion on which any British organization had devoted a whole day to the examination of Nazi doctrines. He regretted the absence of an opposition, which was due to the fact that he had been unable to persuade anyone to speak in support of them.

One general impression gained by the spectator was that the question of race is a focal point where contact is made between specialists in many different branches of knowledge. Some, such as psychologists and demographers, were not represented in the symposium. It is clear that the definition of race and races is primarily the concern of biologists, and several branches of biology are involved. In a secondary way all humanistic sciences are concerned with racial differences, and it is not necessary to stress to-day the importance of the part that dogmas regarding them may play in social, political and international spheres. In order that science may refute the false doctrines with one voice, there is obviously an urgent need for co-operation between the followers of several disciplines, and their deliberations should also indicate a long-term policy of popular education. Marx House is to be congratulated on having encouraged scientific men to abandon their ostrich-like attitude to these matters.

GENETICS AND THE RUSSIAN CONTROVERSY

By DR. K. MATHER

John Innes Horticultural Institution, Merton, London

A CALL to reject in its entirety forty years work in a science which has engaged widespread attention and earned distinction for many, including a Nobel laureate, is both very unusual and very disturbing. Yet this is what Lyssenko and his followers at the Russian Genetical Conference of 1939 would have us do[1]; and, what is still more disturbing, no one other than those directly engaged in genetical research has found it desirable actively to oppose Lyssenko's views. Indeed his allegations have been repeated, and, it would appear, supported, in Great Britain[2].

The situation so created cannot lightly be dismissed by geneticists as the failure of others to appreciate the fundamentals of their subject. It is true that many of the charges are based on a misunderstanding of genetics and its theory, but we must inquire into the reasons why such a misunderstanding can exist. The study of inheritance must have attracted the sympathetic interest of many biologists, especially those engaged in evolutionary studies and the improvement of crops and stock. Yet genetics has apparently proved so disappointing that they do not feel sufficiently concerned to protest at Lyssenko's attack. This implies a sense of frustration, and in order to see how such a feeling could arise, side by side with the rapid development of a sound genetical theory, it is necessary for us to examine the progress of genetical science during its forty years of active propagation.

Gregor Mendel formulated two laws of heredity from which our theory of particulate inheritance has developed[3]. But to do so he devised an experimental technique for investigating genetical differences, and this is, perhaps, his major achievement. Without the technique he could not have made his own discoveries. With the technique he could solve his problems and, what is more, later geneticists could test, modify and extend his laws into the modern theory. Mendel's technique ensured the development of genetical science.

Now this technique of Mendel's depended on the use of single differences. He treated the differences between tall and dwarf, between round and wrinkled seeds. Only when he understood their individual behaviour did he proceed to investigate joint segregations. Once the 3 : 1 single-factor ratio was understood, the 9 : 3 : 3 : 1 and 27 : 9 : 9 : 9 : 3 : 3 : 3 : 1 could easily be interpreted. Thus his success depended on treating the simplest cases first. It is even clearer that the successful analysis of factor interactions, characteristically modifying the 9 : 3 : 3 : 1 into 9 : 7, 15 : 1, 12 : 3 : 1, 9 : 3 : 4 and so on, was impossible until both single-factor and two-factor segregation was fully understood.

Carried to its conclusion this process of investigating segregations of steadily increasing complexity would have led to an attack on the problems raised by those characters, like stature in man, which can only be interpreted as under the control of many genes, and which are hence termed polygenic. The task would have been more formidable than most early Mendelian researches, for these polygenes have individual effects which are small when compared with non-heritable fluctuations. That the approach was, however, then contemplated we may infer from Nilsson-Ehle's discussion of duplicate and triplicate factors in cereals[4]. Furthermore, Emerson and East soon afterwards published a paper on polygenic inheritance in maize[5], and their example was copied by a few other geneticists. But it happened that circumstances, which we shall discuss in a moment, directed interest into other channels. This was the beginning of loss of touch between genetics and the other branches of biology mentioned above; for evolutionary change, as well as the improvement of crops and stock, depends on these complex characters. Species differences and the commercial qualities of plants and animals are polygenic, and it is polygenic, not simple, inheritance which evolutionists and breeders wish to see analysed.

Why then was the attention of geneticists directed elsewhere? There were several contributory reasons. Mendel was not the first man to investigate inheritance, and when his work was re-discovered at the beginning of this century investigations of a different kind were being actively pursued. Galton and Pearson had attempted the analysis of polygenic inheritance, especially in man, by methods quite unlike those of Mendel, and their conclusions were also quite divergent from Mendel's[6]. Thus with Pearson defending biometry and Bateson advocating Mendelism a feud arose, and to geneticists polygenic inheritance assumed a heretical appearance. In the second decade of the century a few geneticists, notably Emerson and East[5] and Fisher[7], showed that the biometrical results could be interpreted as due to the action of many factors behaving in the Mendelian way, but their findings aroused little enthusiasm either in the biometricians or in the Mendelians, who had been, in Great Britain at least, antagonistic for many years. Thus we see that the first reason for the failure to press polygenic analysis was that it had become somewhat improper in the eyes of geneticists.

The second reason was that polygenetics had technical difficulties. Sharp segregations are never shown by polygenic characters and so their analysis requires a combination of genetical and statistical techniques, such as was not then available. If of course interest and enthusiasm had been sufficiently great we may be sure that the necessary technical advances would have been made; but, in point of fact, we can find no contribution to the combination of genetical and biometrical techniques before that of Fisher, Immer and Tedin in 1932[8]. Genetical theory had by this time developed to a stage at which polygenic analysis of a kind impossible fifteen years earlier could be attempted, but slight use has since been made of the methods of these authors. Indeed there is little reason to believe that even to-day the full technical equipment for polygenic analysis is available. Perhaps no single method will be adequate, though selection experiments have proved of considerable value from the time of Johannsen[9] up to the present[10].

In the meantime Mendel's methods had, in Drosophila, led to an astonishing series of advances. Bateson and Punnett discovered, in 1906[11], that unit factors do not always segregate independently. Sex linkage was found shortly afterwards, and the field was clear for the proof of the chromosome theory of heredity, with all its corollaries, when Morgan and his associates began to apply the back-cross technique to *Drosophila melanogaster*. In a very few years sex linkage, the linear order of the genes, non-disjunction of chromosomes, crossing-over and sex balance had all been investigated by this method, and shown to be attributable to the special properties of chromosomes[12]. Here we have the greatest reason of all why polygenetics was neglected. Its technical difficulties stood in such sharp contrast with the basically simple and highly fruitful methods of the 'Drosophilists'. The trickle of papers on polygenic inheritance which had appeared after 1910 almost ceased when the full value of the Drosophila research was apparent to all. Instead similar work was undertaken in maize and other plants, in some cases by the few who had a short time earlier been pursuing polygenic studies.

The first phase of Drosophila genetics was as good as over by 1925 when triploids and attached X females had been investigated. It appeared about this time that interest in polygenic behaviour might be revived by the use of marker genes for the sorting out of complex genetical variation in terms of the chromosomes. In fact one paper of this type, on egg size in Drosophila, appeared in 1924[13], but a new departure in genetical research put paid to this promise. In 1927 Muller[14] announced his discovery that gene mutation could be induced by X-ray treatment and so started a line of investigation which is still being actively pursued. This was followed by Darlington's re-casting of cytology in an inductive-deductive form in the early 1930's[15], by the use of the giant salivary gland chromosomes by Painter in 1934[16], and by Beadle and Ephrussi's investigations on gene action in 1935[17]. Polygenic characters seemed to have sunk completely out of sight under this competition.

Interest was, however, to be revived once more by the turn which genetics has taken towards the experimental study, as opposed to theoretical discussion, of evolution during the last ten years. Though at first attempted by the use of the familiar major mutations this departure forced geneticists to the conclusion that species differences are polygenic (see Timoféeff-Ressovsky and Muller[18]). The stage is again set for an attack on this complex type of inheritance, and, as result of the extra power given to genetical analysis by the chromosome theory and by Fisher's statistical techniques, the opportunity is greater than ever before. Let us hope that it will be seized.

During these forty years of consistent failure to get to grips with the type of inheritance which is, above all others, of importance to evolutionists and breeders, geneticists have not been slow to point out that their science is basic to the practice of research in these other fields. Much of the discussion has been valuable. The theory developed by Fisher, Haldane and Wright has cleared the ground for the new genetical research on problems of evolution, and Timoféeff-Ressovsky, Sturtevant and Dobzhansky have already shown what can be accomplished. But much of the genetical discussion has been unfortunate and harmful, especially in the absence of any experimental results. Though the later geneticists interested in the question have been, to a man, Darwinists, the earlier writers, notably Bateson[19] and de Vries[20], have left a deep mark on the attitude of the average biologist towards genetics, because they continually emphasized the sharply discontinuous nature of variation, when the practical examples of discontinuity to which they could point were generally mutations which appeared, to all but the geneticist, to be almost pathological in their effects on the organism's viability. Here we can see the origin of Lyssenko's attack.

Mendel's discoveries appeared shortly after the "Origin of Species", and we may take it that they would have profoundly affected Darwin's later work if he had been familiar with them. Fisher[21] has shown that the particulate theory of inheritance provides the solution to Darwin's most troublesome difficulty, that of seeing how the store of variability, which Darwin took to be blending, was saved from rapid decay. Darwin accepted this rapid decay and sought to overcome the trouble by assuming an equally rapid replacement by new, or, as we should say, mutational, variation, under the stimulus of novel environmental conditions. This view he developed in "Animals and Plants under Domestication", which Mendel's findings rendered unnecessary as a central part of the theory of evolution. It is thus necessary when discussing genetics and Darwinism, to state which Darwin is concerned, the author of the "Origin of Species" or the author of "Animals and Plants". Genetics is wholly consistent with the "Origin of Species" but has little concern with "Animals and Plants", which in its turn is unnecessary for evolutionary theory.

This effect of particulate inheritance on Darwinian theory was, however, overlooked in the early years of the century. Mendel's paper was re-discovered at a time when small apparently continuous variations were being decried and the younger biologists, of whom Bateson was one, were turning to the view that the variation from which evolutionary change flowed was sharply discontinuous. Mendelian segregation and de Vries 'mutations' in Œnothera apparently fitted so well to this view that they were immediately seized on as good evidence in its favour. It was only much later, when the true nature of de Vries mutations was known[15], and the effects of natural selection on major genes had been considered, that the superficial nature of this evidence was realized. The return to Darwinism and polygenetics then became inevitable. The speculation of Bateson, de Vries and their followers was vitiated by their failure to assess accurately the evolutionary significance of the major variants which they observed, and there was insufficient experimental information to provide an adequate check on this speculation. It is now clear that discontinuous genotypical variation is not incompatible with continuous phenotypical variation; when each of the many genes has a small effect and non-heritable fluctuations occur. Polygenetics integrates genetical discontinuity and Darwin's smooth variation. Bateson and de Vries failed in not seeing that such an integration was possible.

We are now in a position to see Lyssenko's charges in their true perspective. We are not immediately concerned with the method of plant breeding that he advocates. If it should prove sound, its basic theory must be incorporated in genetics; but this is a matter for the future, and in the meantime cannot affect our judgment on his specific charges against genetical theory.

When Lyssenko states that genetics has not contributed very much to the improvements of crops and stock, we must agree with him. In special cases, like the development of autosexing poultry, genetics has been of great value, but these cases are exceptional. The reason for this failure is not, however, that genetics is unsound, but that its development has, owing to a series of historical accidents, been away from the breeders' problems. This may be deplorable, but it provides no ground for pessimism about the contribution that suitable genetical research can make to breeding technique. To deny the potential value of genetics would be as great a misjudgment as that of any geneticist who tried to maintain that his subject had, in the past, given results on which all breeding work must be based. The reality of the present lack of touch is well shown by the way that, at the Russian conference, the bearing of genetics on breeding technique became a matter of personal testament rather than one of analytical discussion.

Secondly, when Lyssenko holds that genetics is anti-Darwin, he is wrong, at least as regards the "Origin of Species", though when he maintains that geneticists have been anti-Darwin he is obviously right. In the absence of appropriate experimental work, the relation of genetics and evolutionary theory has been a subject for unchecked speculation of which much was superficial and unsound. Perhaps the best evidence of the soundness of the genetical approach, as distinct from genetical speculation, is that, in spite of the lack of polygenic research and in face of the utterances of the early Mendelians, geneticists are to-day realizing more and more that small variations are the material of evolution;

though they realize equally that Darwin's argument in "Animals and Plants" is not essential to the theory and may be removed without weakening the general structure in any way.

Finally we come to Lyssenko's condemnation and rejection of what he calls "Morganism-Mendelism". We can see that it arises from a failure to realize the relations of genetical development and the breeder's requirements. He says, in effect, that genetics is useless to the breeder and therefore should be abolished. But astronomy is of no great use to the breeder and yet we do not consider abolishing that science. The real situation is that the particulate and the chromosome theories of heredity are founded on a vast body of fact. They have been tested and re-tested, but never found wanting. Nor has Lyssenko himself any evidence of their alleged unsoundness, though he may have plenty of their faulty interpretation by geneticists themselves and by others. As a case to point, we may take his rejection of pure-line theory on the basis of his observation that intravarietal variation exists in self-fertilizing cereals. The existence of such variation cannot in fact vitiate pure-line theory. Indeed Johannsen himself envisaged this very type of variability[22]. It does, however, show that the application of the theory was faulty because, as Lyssenko discusses it, both mutation and the small amount of out-crossing, known to occur in wheat, oats, etc., are overlooked. It is to the investigation of these agents that attention should be turned, rather than to the alleged unsoundness of misapplied genetical theory.

To call for the rejection of genetical theory is useless; for this theory is sound, no matter how disappointed we may feel that, while developing its internal structure, genetics has neglected those aspects which appeal to the breeder. What is required is experimental research on polygenic behaviour, so that genetical theory may be enlarged until the full potential value of genetics to evolutionist and breeder is realized. The task will doubless be laborious, but the need is obvious and the opportunity great.

ROLE OF PHOTOGRAPHY IN THE DETECTION AND MEASUREMENT OF RADIATION*

By E. R. DAVIES

Director of Research, Kodak, Ltd.

LIGHT which falls on a photographic plate causes the crystals of silver halide, which form the essential constituent of the sensitive layer, to be converted by subsequent development to silver grains, and gives rise to a blackening of the exposed areas. The silver grains can be counted under the microscope, but they provide no direct measure of the incident energy. Although much painstaking work, culminating in the recent theory of Gurney and Mott, has led to a fairly complete understanding of the mechanism of the photographic process, many factors enter in to prevent the establishment of a one-to-one, or other simple, relationship between silver grains and absorbed quanta. Thus the photographic plate cannot be used as a method of absolute measurement of radiation: like the part played by the eye in visual photometry, its role is that of a null instrument for the measurement of an unknown source of radiation by comparison with a known. In addition, and unlike the eye, it provides a permanent record of brightness variations, often over an extended field.

How the photographic plate compares in sensitivity with the eye is a question often asked, and one to which no simple answer can be given. Objects of sufficient brightness to be seen at a glance require an exposure of several minutes to be recorded when a photograph is taken using lenses at present available; yet the existence of distant nebulæ is known only through the use of photography. The photographic plate can integrate radiation falling on it over long periods of time, and it is this ability which constitutes one of its greatest advantages, notably in stellar photography and astrophysics. Moreover, it can be used over a far greater wave-length range than the eye; the recording of ultra-violet lines of spectra provided one of its earliest triumphs; its sensitivity extends into the infra-red; and the great convenience of obtaining a record of the many lines of a source, which may be varying rapidly in intensity, has caused the almost universal use of photography in spectroscopy. X-rays were discovered by their action on the photographic plate, which is sensitive also to γ-rays, cosmic rays, electrons and nuclear particles. Over this wide range, comparative intensity measurements can be made. The accuracy attainable depends on the physicist's knowledge of the characteristics and behaviour of the photographic material and on his ingenuity in devising methods which reduce to a minimum the effect of the many possible sources of error. Under favourable conditions, accuracy of the same order as that possible in visual photometry can be obtained.

The light-sensitive unit is the silver halide crystal. The crystals are usually silver bromide, or mixed crystals of silver bromide with a small percentage of silver iodide, and are of the order of a micron in size. After exposure to light they suffer no visible change, but the affected crystals are completely converted to metallic silver by immersion in certain

---

[*] Substance of a lecture delivered to a joint meeting of the London and Home Counties Branch, Institute of Physics, and the Royal Photographic Society on Feb. 24.

reducing solutions known as developers, and are said, therefore, to contain a latent image. Since the conversion of any crystal to silver is complete, it is not surprising that the fastest photographic materials are those with the largest crystals; but departures are found, and size is not the only determining factor in sensitivity. The silver halides are conductors of electricity. In the dark the conductivity is ionic: it is temperature-sensitive, and at low temperatures falls to zero. On exposure to light there is conductivity at all temperatures, caused by the liberation of electrons; these tend to congregate at any point of low potential energy and to set up a field. Interstitial silver ions, which, ejected by thermal agitation from their lattice position, are responsible for the ionic conductivity, are attracted to the point and form there a speck of silver. This is the latent image which catalyses the process of development.

Thus, sensitivity depends upon the presence of nucleating centres in the crystals before exposure. Without these centres, which are produced in the course of manufacture and are believed to consist of minute traces of silver sulphide, the halide crystals are comparatively insensitive. It is this two-stage process in the formation of the latent image—the release of electrons and the subsequent attraction of silver ions—which is responsible for many of the complex phenomena that are observed. Any radiation that is absorbed will cause the formation of a latent image. The natural absorption of silver bromide is restricted to the blue and ultra-violet, where it is finally limited by the absorption of the gelatin in which the crystals are suspended. The addition of traces of sensitizing dyes results in the formation of a monomolecular coating of the crystals, and the energy absorbed by the dyes is passed on and utilized; in this way the sensitivity has been extended to a wave-length of $1{\cdot}3\mu$; theoretical considerations indicate that an upper limit will be set at about 2μ by thermal energy. The number of quanta required to produce a latent image is not known with any certainty; it probably varies from a few to many hundreds; and the crystals are found to vary widely in sensitivity even when their size is constant, an effect attributable to the need of a suitable nucleating centre. By comparison, high-energy quanta, X-rays, electrons, etc., appear to cause developability upon a single impact.

The photographic effect is conveniently measured by the density of the layer after development and drying. This is defined as the common logarithm of the reciprocal of the transmission, and bears no simple relationship to the number of grains, depending as it does upon size of the grains and upon the method of measurement. Although the silver grains are black, they scatter light appreciably; and the measured density depends to a considerable extent upon the proportion of the scattered light which is collected by the measuring instrument. The effects of exposure and development are usually represented by plotting the density as a function of the logarithm of the exposure; this results in the well-known S-shaped characteristic curve. The position of this curve with respect to the logarithm of exposure axis represents the 'speed' of the photographic material.

Since different materials differ also in the shape of their characteristic curves, the measurement of speed depends to a great extent upon the convention adopted; the choice will be governed by the purpose for which the measurement is required; in spectrography, for example, the reciprocal of the exposure to produce a density of 0·6 is often taken as a convenient measure. The slope of the curve determines the ability of the plate to reveal small object brightness differences; and, by the use of recording materials of high 'contrast', differences of brightness which are invisible can be readily recorded. The shape and position of the curve depend both upon the conditions of exposure and of development, so that it is characteristic of the photographic material in only a limited sense. With increase in the time or temperature of development, the curve increases in slope and tends to shift laterally towards lower exposure values as more and more grains become developed: in general, both contrast and speed increase.

Change of absorption with wave-length can cause the slope of the characteristic curve to change; exposure to ultra-violet light, which is strongly absorbed, leads to curves of much lower slope. The time of exposure is a factor of great importance. The photographic plate is not a perfect integrator of radiation: an x-times reduction in intensity cannot be made up for by an x-times increase in exposure time. Thus intensity and time are not reciprocal quantities, and the photographic plate is said to show failure of the 'reciprocity law'. If, therefore, the logarithm of the exposure (intensity × time) necessary to produce a given density is plotted as a function of exposure time, instead of a horizontal straight line being obtained, the curve passes through a minimum, which, with many materials, occurs at times of the order of 1 second. At both shorter times (higher intensities) and longer times (lower intensities), more exposure is necessary to produce the given result.

These departures, which are of great importance in many problems of photographic photometry, are the direct result of the two-stage formation of the latent image. At high intensities, the second stage—the moving up of the silver ions—does not take place quickly enough; the capacity of the nucleating centres for electrons is limited; some are repelled before they are neutralized by the silver ions, and the size of the silver speck is therefore reduced. At low intensities, the nucleating centres build up slowly: in the early stages of their growth they are not stable and tend to lose electrons by thermal agitation; considering the same total number of quanta incident on a crystal, the greater the rate at which they are received the greater their effect. In the extreme case, unless the rate of reception of quanta is more than sufficient to counterbalance the loss by thermal agitation, no duration of exposure will give a photographic effect. Thus, in astronomy, success depends upon the size of the telescope used, since this governs the brightness of the stellar image; prolonged exposure with small telescopes fails to reveal the fainter stars detectable by larger instruments. The shape of the so-called reciprocity curve can be modified in several ways. If the temperature is lowered during exposure, the mobility of the silver ions is decreased and the sensitivity at high intensities is thereby decreased, but at low intensities the sensitivity is increased, since the latent image becomes more stable. Use has been made of this effect in astronomy, and plates have been cooled to a temperature of solid carbon dioxide during exposure in order to increase their sensitivity.

The addition of a uniform exposure has interesting and useful results. The sensitivity of the plate may be increased either by a uniform exposure before the camera exposure or after it, depending upon the actual time of the camera exposure; when this is long, as in the photography of faint celestial objects, the sensitizing exposure must take place beforehand and must consist in a short flashing of the plate; when the camera exposure is relatively short, the uniform exposure must follow and must be to a low intensity for a long time. In either case, the added exposure is adjusted in amount to produce only a small general fogging which does not greatly affect the interpretation of the record. Uniform after-exposure or pre-exposure can thus be useful, if applied deliberately; but equally they may lead to serious errors if they occur accidentally and pass unrecognized.

A manifestation of reciprocity failure that has long been recognized as a source of error in photographic photometry is the intermittency effect: an exposure given intermittently may produce a greater, or lesser, density than when the same total exposure is received continuously. Quite recently it has been shown that, if the interruptions are sufficiently rapid, the effect is the same as that produced by a continuous exposure of an intensity equal to the *average* intensity of the intermittent exposure. The frequency of interruptions must be so high that on the average each grain receives only one quantum during each separate exposure. Owing to the small size of the grains, the critical frequency is not as high as might be imagined: an exposure of one second duration need be interrupted at a rate of only a hundred per second. From being a source of error, valuable use can now be made of the effect: by rotating sectors at high speed, variations in time can be converted effectively into variations in intensity. Apart from the occasional advantages that can be made of these effects of reciprocity failure, the fact of importance in photographic photometry is that the calibrating exposure should always be of the same duration as the exposure to the unknown source. There are only two exceptions to this rule: X-rays, and other high energy quanta, because they make a grain developable by a single impact, show no reciprocity failure; the log It/log t curves for different wave-lengths are always parallel. If, then, during the process of calibration, one spectrum line is reduced in intensity until it matches in density another line of the same spectrum, the relative energy of which is known, the result will be independent of the exposure time; so that, in certain cases, the calibrating exposure need not be of the same duration as the unknown.

The general rules of photographic photometry follow readily from what has been said. The calibrating exposure should always be impressed on the plate used for recording the unknown radiation, so that errors of development may be reduced. Whenever possible, the two exposures should be made on contiguous areas, since the plate may show small local variations in sensitivity. The spectral composition of the calibrating radiation should be identical to that of the unknown radiation, although in spectrophotometry within narrow spectral regions it is permissible to use a mean wave-length for the calibrating radiation, for example, by the use of sharp cutting filters. The time of exposure must be the same for both exposures, apart from the two exceptions mentioned.

It has been assumed that the exposed areas are large and that edge effects can therefore be neglected: the sensitive layer has been imagined to be a two-dimensional continuum, and any effects caused by its finite thickness have been ignored. During the course of manufacture, the photographic 'emulsion', which is a suspension of silver halide in a solution of gelatin, is coated evenly on to its support, and dries down to form a layer about one thousandth of an inch in thickness. During development, the layer swells to some five times this thickness. The images to be recorded are often of comparable dimensions, for example, the image of a star or of a spectral line; and second-order effects arise, owing both to the penetration of the light and the penetration of the developer. The light is strongly scattered on entering the layer, and a sideways spreading of the image results: the developer solution reaches the grains by diffusion, and the products of the chemical reaction diffuse outwards; they inhibit the reaction and produce local variations which may sometimes cause the density distribution of an image to depart seriously from its true form. Full development and vigorous agitation of the developing solution over the surface of the plate will generally reduce these effects to negligible proportions; but the effect of light scatter is not so easily overcome. Use can sometimes be made of this, as in astrophysics, where the growth of the image with exposure is used as a measure of stellar magnitude. More often the scatter tends to destroy the fine detail of the image, and can be limited only by the best choice of materials. The effect depends both on the grain size and the number of grains per unit volume of the layer, as well as on the wave-length of the light; and the finest grain emulsions are not necessarily those which scatter least. The discrete nature of the developed image also plays a part in the detection of fine detail. A microdensitometer record of a uniformly exposed and developed area shows irregularities caused by this granularity of the image; variations due to this cause will be superimposed on those which are the subject of investigation, and will tend to mask them. The graininess increases both with the density of the image and with the size of the grains; its effect on visibility tends to outweigh that of light scatter, so that slower emulsions almost invariably have greater resolving power than faster ones. An additional reason is that slower emulsions generally have higher contrast, and this naturally increases the ability to differentiate small brightness differences.

It is not surprising that an almost bewildering array of photographic materials is available. The choice must depend upon the problem in hand. Sometimes the need is for high resolving power and for low graininess; at other times, these desirable features must be sacrificed for extreme speed for some part of the spectrum; and consequently a compromise must usually be made.

OBITUARIES

Prof. A. W. Nash

ALFRED WILLIAM NASH, professor of oil engineering and refining at the University of Birmingham, died in his fifty-sixth year at his home in Solihull on March 14. After training as a mechanical engineer at King's College, London, he had some experience in dock construction in Hong-Kong, and shortly afterwards joined the (then) Anglo-Persian Oil Company and took part in the building of the great refinery in Abadan, South Persia. In 1913 he proceeded to the Caucasian oil territory and remained in Russia for more than five years, chiefly engaged in field production problems.

Then began Nash's long and successful career in Birmingham in the footsteps of that great pioneer, the late Lord Cadman, who had founded the first school of petroleum technology in Great Britain under his charge as professor of mining. When Cadman left, the chair was divided and a separate professorship of oil technology was established, and in 1924 Nash was appointed to the post. A very substantial endowment of £125,000 had been raised by the great British oil companies, and Nash's first task was to erect a block of laboratories, offices, museum and library to house his school. This was opened in 1926 and remains as his chief monument.

During his whole career in Birmingham, Nash was responsible for a constant stream of scientific contributions to oil technology. He was a man of ideas and well able to stimulate his staff and students. With his ample background of first-hand experience in oil-fields and refineries, he was well equipped to sense the relative importance of both practical and academic problems, and to direct a vigorous and progressive school of research, while in the course of his many visits to centres of oil activity in America, Europe and the East he made innumerable contacts with the men on the spot, and thus realized the need for investigation on this or that project.

Throughout his active life he was intimately concerned with the affairs of the Institute of Petroleum —known, when he became a member in 1914, as the Institution of Petroleum Technologists. For many years he served on the Council and as vice-president; three years ago he was elected president, and he died in that office. Most of his contributions to science are to be found in the pages of its *Journal*, but he was a prolific worker, and many of his papers appeared in American technical journals.

In collaboration with his colleague Dr. Bowen he wrote "The Principles and Practice of Lubrication"; with Dr. D. A. Howes, "The Principles of Motor Fuel Preparation and Application"; and he played a great part in the organization and editing of the four volumes of "The Science of Petroleum". His work with Howes on knock-rating of pure hydrocarbons was of great merit; he demonstrated the synthesis of lubricants from the simple olefines by polymerization; with Hunter he developed the fundamental study of solvent extraction, the dewaxing of lubricating oil and the refining of waxes. With Dr. A. H. Nissan he published a valuable paper on the relation between viscosity and constitution. His presidential address on "Petroleum as a Raw Material" showed real insight into the ever-growing utilization of oil and its gaseous by-products as raw materials for chemical syntheses.

This brief note would be very incomplete did I not pay a personal tribute to my old and valued friend and collaborator. Nash had a most lovable nature, and those of us who enjoyed his close friendship for many years feel his passing acutely. Especially will he be missed by his old students who, working in all parts of the world, always kept in touch with him, and were always delighted to visit him on their return home.

A. E. Dunstan.

We regret to announce the following deaths:

Dr. B. M. Griffiths, formerly reader in botany and head of the Department of Botany in the University of Durham, on March 25, aged fifty-five.

Mr. R. W. Haydon, formerly lecturer in agriculture, University of Leeds, on March 28.

Mr. H. J. Hughes, formerly principal of the Muresk Agricultural College, Western Australia, on September 27, aged sixty-seven.

Dr. T. B. Macaulay, formerly president of the Sun Life Assurance Company of Canada, founder of the Macaulay Institute of Soil Research at Aberdeen, on April 3, aged eighty-one.

Mr. F. J. Rae, director of the Melbourne Botanic Gardens and Government botanist for Victoria, on September 18.

Mr. L. Wray, I.S.O., formerly director of the State Museums, Malaya, on March 14, aged eighty-nine.

NEWS and VIEWS

India

The breakdown of the negotiations conducted by Sir Stafford Cripps on behalf of the British Government with the chief Indian communities for a settlement of relations between the British and Indian peoples is a cause for profound regret. At a time like the present, every jarring note in the concord of the free nations is eagerly awaited in the Axis camp, and is represented by every device of propaganda as a major disaster. This it certainly is not, for although the leading communities in India have been unable to agree either among themselves or with the British Government on any immediate change in the form of government of the country, on the major issue, namely, resistance to aggression, there has been striking agreement. Further, the various parties have been able to put their views to a member of the British Cabinet, and have themselves been able to study concrete proposals for a settlement. The fundamental stumbling block is clearly lack of mutual understanding and sympathy, and, one fears, an under-estimate of the complex factors involved in ruling a sub-continent. The old divisions and the old distrust are still painfully apparent. As Sir Stafford Cripps said in his farewell broadcast to the Indian people: "Someday, somehow, the great communities and parties in India will have to agree upon a method of framing their new constitution". The problem will have to be approached in the scientific manner, assembling all the data and weighing them without prejudice, in the sure hope that a true solution will eventually be found.

Science and Ethics: A Hindu View

The symposium on science and ethics, opened by Dr. C. H. Waddington, which appeared in these columns during September and October of last year, aroused world-wide interest. We have already published a communication from Prof. Chauncey D. Leake, who was chairman of a discussion on the same topic by American biologists; and we hear that the Aristotelian Society is arranging a meeting early in June at which Dr. Waddington will be invited to defend his views. A comment on the symposium by D. V. Gundappa was published in the Indian journal *Current Science* in December last, and a revised and enlarged reprint of his remarks has just reached us. Mr. Gundappa emphasizes the lack of agreement between the contributors to the symposium, and states his own view "that the data which science in its present state can furnish . . . for a theory of ethics or metaphysics are a field of quicksand". He then presents an extremely valuable summary of the Hindu philosophy of ethics, which, as he rightly points out, is only too little understood in Great Britain. Its elaborate structure and the mystical nature of its concepts will probably always make it difficult for non-Hindus to comprehend, but Mr. Gundappa's account, which is short and admirably clear, should serve as a most useful introduction to this important phase of human thought.

Federal Union and Peace Aims

WRITING with reference to recent articles in NATURE on reconstruction, the Federal Union Ltd., 3 Gower Street, London, W.C.1, has forwarded to us a resolution relating to the "Peace Aim—War Weapon" report prepared by its Peace Aims Committee, and passed by representatives of 150 branches of this movement at the annual general meeting held at Eastertide. The resolution reads: "Lack of unity among the United Nations can lose both the war and the peace, and we therefore call upon the Government to cement their unity by the following methods: (1) Inviting Russian and Chinese representation on the joint commissions directing Anglo-American strategy and supply. (2) Pressing our Allies to set up an Allied Political Warfare Board. (3) Appointing an Allied Reconstruction Commission whose task would be to draw up a draft treaty outlining the world organization which should arise out of this war; this treaty to include plans for a nucleus democratic federation open to the members of such a world organization. The Allied Reconstruction Commission should define in a Twentieth Century Charter of Rights the political and social objectives which must be the foundation of both world organization and democratic federation. (4) Setting up, in conjunction with those of their Allies which have democratic governments in control of their countries, an International Consultative Parliament to advise the various Governments on the conduct of the war and to draft a provisional federal constitution."

Books for Damaged University Libraries

THE Committee on International Relations of the British Federation of University Women, at present at 16 King Street, Reading, Berkshire, points out that during the present hunt for salvage many books and journals are being sent for pulping which would yield only a small contribution to the War effort but a much greater contribution to the restoration of universities. The British Federation of University Women is therefore trying to collect books and journals suitable for academic libraries. The Committee would like to have particulars of suitable books and spare sets, volumes, or even odd numbers of scientific and similar journals. If possible, the Committee would like the donors to keep these books until the end of the War, as it is safer to have them dispersed, but depots will be arranged if necessary to which the books may be sent. The British Federation of University Women hopes by these steps to be ready, when peace comes, to help fill the many gaps made in university libraries in Great Britain and elsewhere by enemy action; this would be an important step in the reconstruction of university life.

Feeding Factory Workers in the United States

THE Council on Foods and Nutrition and the Council on Industrial Health of the American Medical Association have condemned the indiscriminate giving of vitamin pills to factory workers. They state that at the present time there is no body of scientific information on which to base the recommendation that industry as a whole adopt such a practice, which is irrational from the therapeutic point of view, unwise from the nutritional point of view and uneconomical; instead, firms should support research on nutrition among their workers. The Councils recommend a balanced diet of natural foods, and it is stressed that calories are the most important consideration. "No amounts of vitamins and essential mineral nutrients can obviate this need for energy. Furthermore, if wholesome natural foods are used as the source of the needed calories, the required vitamins and minerals will be secured automatically because they are contained in these natural foods." Reference is made to the stress laid in Great Britain on the provision of factory canteens where at least one good meal each day is provided; it is suggested that employers avail themselves of accurate data on diet from authorized Federal or State agencies, and, under proper direction, teach individual workers the bases of nutrition and through them their wives. The report closes with a reminder that nothing in the Councils' statements is intended to belittle the significance of vitamins in nutrition, or the value of the proper use of added vitamins in improving staple foods such as bread and flour.

Technically Trained Chemists in the United States

THE Defense Committee of the American Chemical Society has issued a report on a survey of one hundred and eighteen colleges and twenty-nine chemical corporations in the United States in connexion with the American war effort. It is reported that essential industry needs in 1942 from 2,000 to 3,000 more chemists and chemical engineers than will be graduated or are otherwise available. The official statement reads: "The Army and Navy are deeply concerned. Investigations made by this organization prove that trained personnel to produce this material [munitions] is lacking. Not only the finished product but also the raw material going into smokeless powder, rubber, etc., can be produced only under the active control of experienced chemists and chemical engineers. There is far greater immediate danger to the ultimate outcome of the war from shortages of such man-power than there is from any lack of officers and men in the combat force. Without production of essential materials the war will be lost, since the combat forces can not exist without material."

Earthquake in New Guinea on January 27

THE United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has provisionally determined the epicentre of the earthquake of January 27 last, which occurred at 13h. 29·4m. U.T. The determination was based on instrumental reports from seismographic stations at St. Louis, Tucson, College, Logan, San Juan, Pasadena, Philadelphia, Lincoln and Fordham. The epicentre appeared to be in the region of Geelvink Bay in western New Guinea. The region of and around New Guinea appears to contain, in addition to active centres of activity, both active and semi-active volcanoes. An earthquake with epicentre some two miles south-east of Rabaul (New Britain) occurred on May 7, 1919, in the neighbourhood of the semi-active volcano Glaie or Tavurur. One previous to this was on January 1, 1916. The line of disturbance is south-west from the volcano Glaie to the large active volcano called the Father on the north coast of New Britain. Earthquakes appear to be most severe when the Father is quietest. The line extends then westerly towards the west end of New Britain, where there are semi-active volcanoes; thence on to the island of Manam off the coast of New Guinea, where there is a very active volcano. The present seismic activity appears either to be on another branch of this line of activity, or along a westward extension of the line.

Earthquake in the Philippines

An earthquake of considerable severity was registered at both the Riverview and Perth Observatories in Australia on April 9 early in the day. At Perth the seismograph pendulum boom swung five inches, and at Riverview the seismograph showed earthquake waves passing the observatory for four hours. It was tentatively suggested that the earthquake might have had its epicentre under the sea south-west of Luzon in the Philippines.

Rainfall Flooding and Health

A Chadwick Lecture under the Bossom Gift was given on April 14 by Mr. D. C. Graham, who discussed the dangers from rainfall in urban areas, the prevention of flooding of buildings and of its insanitary consequences. Mr. Graham dealt with the subject under four headings: (1) faulty design of buildings and omissions of essentials; (2) overflowing of streams and rivers; (3) damp and flooding by land water; (4) backing up of rainwater in drains and sewers. The first two causes were touched on and the two last discussed in detail. Reference was made to the importance of the building by-laws in this connexion and to the necessity of careful inspection and repair of river walls. As regards the third cause, there is considerable difficulty in ascertaining in dry weather whether a building site will remain dry and whether there are any land drains or filled-in ditches that will cause dampness or flooding after heavy rain. The varying levels of the land water due to drought, pumping near the site and to wells and the great importance of constructing the lowest floors of building either above the maximum water level or making the walls and floors waterproof and of sufficient strength, were dealt with, as well as the aying of sub-soil drains near a building, and what hey should and should not do. It is not practicable or financial and other reasons to provide sewers of ufficient capacity to carry away the heavy rainfalls hat occur from time to time, especially during hunderstorms, as rapidly as they fall, and there are number of unknown factors, such as the storage apacity of the sewers and drains and the fact that during a storm the flow in the sewers may be backards as well as forwards, which prevent precise alculations being made. Where it is necessary to onstruct basements with floors below the possible ood level in the sewers, there are advantages in not raining such basements; where such basement rainage is required in old or new buildings, the risk f flooding can be reduced to a minimum at no great xpense.

Freshwater Fish Farming

The Freshwater Biological Association of the British Empire has just published a pamphlet on the "Production of Freshwater Fish for Food" by Dr. T. T. Macan, Dr. C. H. Mortimer and Dr. E. B. Worthington (Freshwater Biological Association, Wray Castle, Ambleside, Westmorland, Sci. Pub. No. 6, pp. 36. Price to non-members 1*s*. 6*d*.) Fresh water covers about 340 square miles in England and Wales and about a similar area in Scotland. The total area is, therefore, comparatively small; but in war-time these inland waters should not be neglected since they can yield crops of food at the cost of little labour. The chief aim of the pamphlet is to make available some of the methods, especially those involving the use of manures, by which crops of fish from fresh water can be increased. The most suitable fish for stocking ponds are carp (*Cyprinus carpio*), tench (*Tinca tinca*) and rainbow trout (*Salmo irideus*). Other freshwater fish are considered, though most of them are unsuitable for rearing in ponds. Perch, for example, tend to become too numerous, and a method of perch trapping is described in the pamphlet (see also Nature, 148, 651; 1941). Improvements in eel fishing are also discussed. Other topics considered in the pamphlet are: the food chain in natural waters, productivity of natural waters, methods of increasing productivity, pond management and construction, stocking and cropping, lay-out of a carp farm, sewage fishponds. Anyone possessing a pond or concerned in any way with areas of fresh water of reasonable size should obtain a copy of this pamphlet.

Air-raid Damage and Electricity Supply

In its issues of March 13 and 20, the *Electrical Review* publishes the results of a works investigation by E. A. Beavis of cable breakdowns due to bomb damage and the resulting short-circuits, the implications of which, on a cable of comparatively small cross-section, seem to warrant careful consideration by power distribution engineers (see also Nature of February 7, p. 173, and March 28, p. 362). This cable, having an area of 0·023 sq. in., was insulated for 11 kv. and provided with a B.O.T. sheath and a lead sheath which was double steel-tape armoured and served. It had operated since 1926 on a 6·6 kv. system. During a severe raid, a bomb explosion damaged the cable at a point 708 yd. from the main sub-station and also a 0·10-sq. in., 3-core, 6·6 kv. cable running close by along the same route. The switch controlling the 0·023-sq. in. cable did not trip, although the 0·10-sq. in. cable was tripped out on short-circuit protection. Excavation disclosed damaged places in the 0·023-sq. in. cable at five points within a distance of about 150 yd. from the main sub-station. The faults were cut out and removed for examination. With the exception of No. 5—the farthest from the station—all the failures showed similar characteristics and in appearance were more like bursts or blow-outs than true electrical faults.

At fault No. 5 the cable had burst completely, one steel tape only holding the parts together. At the break, the conductor strands showed signs of fusing, while the lead sheath also had been partly melted; a short-circuit had evidently occurred at this particular spot. From the collected evidence, it seems that two distinct breakdowns occurred, the first of which was at the crater caused by the explosion and the second at fault No. 5. From a consideration of the circuit conditions prevailing it was concluded that from the very outset the 0·023-sq. in. cable was too small to be able to deal with the large fault kva. capacity available—approximately 260,000 kva. at the main sub-station. A factor contributing largely to the excessive damage occasioned was the comparatively long time-delay in the switch tripping arrangements; with a minimum relay setting of practically 0·9 sec. and a switch action taking 0·4 sec., the total clearance time was almost 1·3 sec. Had this operation been much quicker, say 0·4 sec. or less, the temperature would not have reached 200° C. and the deterioration in the cable would not have been excessive. The second part of the article gives a theoretical study of the factors involved in co-ordinating cable size with system characteristics from the point of view of the large fault kva. likely to be experienced.

Bio-Physics in the United States

The growing importance of bio-physics is recognized in a new feature of the *Review of Scientific Instruments*, published by the American Institute of Physics. Starting with the new volume, 13, the scope of the journal is enlarged to include physical instruments useful in biological research. In the issue dated January 1942, Detler W. Bronk discusses physical instruments for the biologist. Reference is made to the outstanding work of Helmholtz, Keith Lucas and A. V. Hill in the combined fields of physics and biology. Progress in the physical sciences is soon reflected in the advance of biology and medicine. As these sciences become more analytical, more revealing methods of observation, more precise instruments for measurement and more accurate means for the control of experimental conditions are needed. Investigators have extended their large-scale analyses down to the small scale of the activity of the cellular units of the organism and their molecular structure. This requires extraordinary sensitivity and high resolving power in the instruments. Furthermore, some of the phenomena occur with great rapidity.

One of the great faults of extreme specialization lies in the tendency to produce journals of similar extreme specialization, so that workers in the restricted field need 'waste' no time in reading outside their subject. As a result they are often ignorant of fields where their own specialized knowledge would be of the greatest help. The danger is very great in biophysics. Whereas every medical student must spend a part of his time studying physics, it is quite unusual for the physicist ever to have studied biology. Time-tables in universities often prevent a student including one of the biological sciences in a course involving both physics and mathematics. The new development, by which papers on biophysics will be included in a journal devoted to general physics, will prove unusually valuable in directing the attention of physicists to a new field containing problems of which many may be quite unaware. The first three papers in the new section deal respectively with an analyser for 1 c.c. of respiratory gas, with volumetric microrespirometers capable of an accuracy of the order of 1/100 mm.^{3} an hour and with an electrical capacitance diaphragm manometer for direct pressure measurements in the arterial blood stream. This latter instrument uses a radio-frequency, crystal-controlled oscillator and a pressure-sensitive condenser in the pick-up unit.

The Direct-Current Amplifier in Industry

In a paper read before the Institution of Electrical Engineers on March 6, D. C. Gall describes the design and behaviour of a direct-current amplifier, entirely alternating-current mains-operated, and having an accuracy independent of mains' fluctuations or change in valve characteristics. The voltage to be amplified is applied to a reflecting galvanometer in series with a resistance. The light from the galvanometer strikes a photo-cell which controls the grid voltage of a thyratron valve, this voltage shifting according to the illumination of the photo-cell. The grid voltage makes the thyratron conducting between its anode and filament circuit for part of the positive half-wave and, as the phase of the grid voltage advances, the conducting period lengthens, giving a larger effective rectifier current output. This current is fed back through the resistance so that the voltage drop opposes the applied voltage, the drop rising until the input voltage is balanced. Output current is thus proportional to input voltage. The thyratron anode current is supplied from a 250v.-section of the mains transformer and it operates the amplifier output circuit apparatus. Smoothing condensers and inductances convert the thyratron unidirectional current pulses into steady direct current and suppressing circuits eliminate radio interference from these pulses. The amplifier has an output of three watts and a power gain of about 10^{10}. It can be used as a voltage- or current-amplifier and is extremely stable. It has been applied to high-speed temperature-recording of liquid steel, to the metering of heat transport in large hot-water plants, to optical pyrometry, measurements of illumination by barrier-layer type photo-cells, to the polarograph and to many other problems in which very small E.M.F.'s are available as a function of the quantity to be measured. The departure from linearity of response is of the order of only a few parts in 10,000, and voltages of a few microvolts and currents as low as 0·01 microamp. can be amplified and thus used to operate recorders and controllers.

Uses of Laminated Densified Wood

An article by A. E. L. Jervis in the *Electrical Review* of March 27 describes the insulating properties and tooling applications of the so-called densified woods. In contrast to the mechanical shortcomings of solid wood, the laminated densified varieties are very strong and can be good electrical insulators, resisting corrosion and acid as well as moisture absorption, in which respect those produced under greatest pressure with the largest resin impregnation content appear to afford the best results. They can be substituted for metals, being more suitable (one sixth the weight of steel) in some cases, easier to machine and modify, and more quickly produced in a variety of thicknesses and shapes, so lending themselves to mass fabrication. Laminated densified woods can have tensile strengths up to 34,000 lb. per sq. in. and compressive strengths between 18,000 and 30,000 lb. per sq. in., depending upon veneer orientation with respect to the direction of the wood grain. Fanwise arrangement of the veneer laminations is suited to the manufacture of circular articles; 45° stacking is a simplification, and a 90° arrangement is the standard for material used for aircraft tool-making.

Two varieties are made by Moulded Component (Jablo), Ltd., both being produced hot under pressure

One grade, 'Jabroc', consists of alternate laminations of wood veneers and glue films and is used primarily for its mechanical superiority when electrical stressing is light. The dielectrically better 'Insul-Jabroc' consists of impregnated veneers only and is essentially an insulator for use indoors, out of doors, or under oil. Electric strength tests made on two 0·25-in. thick 'Insul-Jabroc' boards selected at random, each consisting of twenty-one veneers of beech wood, resulted in puncture at 65 kv. when impregnated with cresol resin, and at 62·5 kv. with phenol resin. Applications of densified wood are generally similar to those of the better-known moulded plastic substances; a typical electrical example is instrument panels aboard ships, while as a secondary dielectric it can be used for insulator spindles for overhead power lines. It also finds application in the fabrication of air screws and in the manufacture of tools for the aircraft industry, where its lightness can be an important factor in the increasing amount of female labour being employed in factories. In some cases in which girls have been unable to handle large steel jigs, for example, the introduction of laminated materials may effect up to 80 per cent saving in tool weights.

Cellulose Acetate Yarn for Wire Insulation

In an article by D. R. Brobst (*Bell Lab. Rec.*, 20, No. 5; 1942) it is pointed out that, about twenty years ago, a preliminary investigation was made on cellulose acetate yarn samples which indicated that its electrical properties are superior to those of silk. By 1925 the trend towards the use of acetate yarn in the textile industry was accompanied by the establishment of several plants in the United States to produce this yarn. Trial installations were made in several telephone offices, primarily to determine the handling characteristics of the material during manufacture and installation, and to obtain data on the service ageing properties. At first, mechanical difficulties experienced in handling the wire offset the price difference between the silk and acetate yarn so that no economic advantage could be obtained by its adoption. With further expansion in the use of acetate yarn in the textile industry and the resulting reduction in price, methods of handling were developed so that the yarn could be used in regular manufacturing processes without difficulty. The advantage to be gained from the use of acetate yarn from the point of view of electrical characteristics and price not only warranted substitution of this material for silk in silk and cotton insulated wires, but also amply justified the use of a wire with double wrappings of acetate yarn, a single wrapping of cotton and a lacquer coating, in place of wire which had been made with a double wrapping of cotton and cellulose acetate coating.

Card Index of X-ray Diffraction Data

A 4,000-card file index of X-ray diffraction data for use in the Hanawalt method of chemical analysis by X-ray diffraction has recently been published by the American Society for Testing Materials. This compilation is sponsored by a joint committee of the Society and the National Research Council, under the chairmanship of Prof. Wheeler P. Davey, Pennsylvania State College. The data include not only those obtained by Dr. J. D. Hanawalt and his associates and contributed by the Dow Chemical Co., with later corrections, but also additional data that have been contributed by the Aluminum Co. of America, the New Jersey Zinc Co., together with data taken from the technical literature in the English language. The cards give all pertinent data found in the sources, with provision for insertion of accessory data such as crystal structure, density, etc. The index identifies the strongest three lines in the X-ray diffraction pattern of some 1,300 crystalline compounds, the chemical names and symbols of which are as given by the various sources. The Hanawalt method has been described in the technical literature and a committee of the American Society for Testing Materials is perfecting a tentative recommended practice for the identification of crystalline materials by the X-ray diffraction method. Copies of the index, packed in finished container boxes, can be obtained from the American Society for Testing Materials, 260 S. Broad Street, at 50 dollars per set.

Leeches

Unlike the L.M.B.C. Memoirs, from which they admittedly received their inspiration, the Indian Zoological Memoirs are not confined to the description of marine organisms, and the most recent to be published under the able editorship of Prof. K. N. Bahl is No. 8 on Hirudinaria, the Indian cattle leech (Lucknow, 1941), by Dr. M. L. Bhatia. Those instructors in Great Britain faced with providing senior students with class material will read with envy that *H. granulosa*, the type chosen, is common in India and that fully grown specimens attain a length of 12–14 in. This monograph is a straightforward and readable account of Hirudinaria from a number of different points of view, and the frontispiece is a coloured plate of the entire animal. In the first chapter the classification is dealt with, and an adequate review of the systematics of the Hirudinea is provided in order to show the position and relationships of Hirudinaria to the other leeches. The family Hirudidæ, to which it belongs, and the genus Hirudinaria are naturally more fully dealt with than the remainder. The main part of the book contains a very good account of the anatomy and histology of the leech illustrated by clear drawings, but it is permissible to pick out two chapters as being exceptionally useful. These are the ones dealing with the cœlom and hæmocœl system and the excretory system, matters that receive inadequate treatment in most text-books. Altogether the monograph reaches a high level, and is particularly welcome since the information it contains, most of which applies with slight modification to Hirudo, is not readily available to the ordinary student. Author, editor and publisher alike deserve the congratulations and thanks of zoologists not only in India but in other countries as well.

Medical Advances in the Argentine

In a recent paper (*Bol. Ofic. San. Panamericana*, 20, 1265, 1941) Dr. B. A. Houssay, director of the Institute of Physiology in the University of Buenos Aires, surveys some of the more important contributions to medical science in the Argentine during the last few years. The work at the Institute of Physiology includes studies of the role of the anterior pituitary lobe in carbohydrate metabolism and diabetes, hypertension of renal origin, fluorosis, the role and regulation of plasma potassium, the normal and pathological physiology of urobilin and bilirubin, the sex hormones and the interaction of the glands of internal secretion. At the Institute of Nutrition directed by Prof. Escudero research work was done on milk, dietetics of childhood, national foods and vitamin C. At the Institute of Experimental Medicine directed by Prof. A. H. Roffo investigation was carried out on the carcinogenic action of tars (from coffee, tea, maté and tobacco), of derivatives of irradiated cholesterol, of diets based on cooked fats and of the production of cutaneous cancer in rats repeatedly subjected to the action of the sun and ultra-violet rays. The Bacteriological Institute of the National Department of Health directed by Prof. Sordelli not only prepares sera, vaccines and hormones, but also carries out research work on various infectious diseases such as brucellosis, bacillary dysentery, enteric fever, sylvatic plague, psittacosis, trypanosomiasis, uncinariasis, influenza and typhus. Important investigations have also been made on the adrenals and vitamin A at the Institutes of Physiology and Pharmacology of Rosario, and on endocrinology, electrocardiography and blood groups, at the Institute of Physiology at Córdoba.

Artificial Insemination of Cattle

ARTIFICIAL insemination of animals has been applied for some years in a number of countries. Advantages claimed for the practice are the lessening of the risk of spread of disease in livestock, reduction in sterility and increase in fertility, facilitation of improvement in quality, and economy in livestock management. Trials of artificial insemination of cows on a practical scale have been recommended by the Agricultural Improvement Council for England and Wales to be carried out in the first place at two centres, Cambridge and Reading, by the Cambridge School of Agriculture and the National Institute for Research in Dairying respectively, under the guidance of a supervisory committee and with the assistance of local committees for the two areas. The supervisory committee is as follows: Prof. J. Scott Watson (chairman), Prof. J. F. Craig, Mr. J. H. Everall, Dr. John Hammond, Mr. Robert Hobbs, Mr. P. A. Mytton, Mr. C. Nevile, Capt. J. Templeton.

Horticultural Composts

WORK upon the scientific mixing of composts performed at the John Innes Horticultural Institution has been condensed into a useful short paper by W. J. C. Lawrence (*J. Roy. Hort. Soc.*, 67, Pt. 3; March 1942). The new composts involve the use of sterile peat and very coarse sand for the improvement of texture, partial sterilization of turf loam by steam to eliminate harmful organisms and substances, and the addition of "John Innes base", a mixture of fertilizers. This base consists of a slowly available nitrogenous manure, a preponderance of superphosphate, and a little sulphate of potash. Details for the mixing of seed and potting composts are given in the paper, and fuller details are available in a leaflet (from the Institution, 31 Mostyn Road, London, S.W.19, price 6*d.*).

Two Early Plant Collectors

A SHORT paper by the Right Rev. J. W. Hunkin, Bishop of Truro (*J. Roy. Hort. Soc.*, 67, Pt. 2; Feb., 1942) describes the work of William and Thomas Lobb, two of the first plant collectors employed by James Veitch and Sons about 1840. William was responsible for such familiar introductions as *Berberis Darwinii* and *Escallonia macrantha* from Chile, while Thomas brought many new rhododendrons and orchids from Malaya.

Royal Society of Edinburgh Year Book

IN 1940 it was decided that the *Proceedings of the Royal Society of Edinburgh* should be published in two sections, "A" (Mathematical and Physical) and "B" (Biological), and the appendixes and certain other matter issued separately. The first issue of this additional material has now appeared under the title of "Year Book of the Royal Society of Edinburgh, 1940–1941" (price 5*s.*). It includes obituary notices, brief 'proceedings' of the meetings held during the session, lists of recent awards of the Society's medals, etc., membership list, and the laws of the Society. It will be very convenient to have these details of the constitution and activities of the Society in separate and handy form for reference purposes.

Announcements

DR. CHARLES OLMSTED, of the Department of Botany of the University of Chicago, has been appointed botanical editor of *Ecology*. He succeeds Prof. Francis Ramaley, of the University of Colorado. Prof. Thomas Park, of the Hull Zoological Laboratory of the University of Chicago, remains editor for zoology.

PROF. ADOLF WINDAUS, professor of chemistry in the University of Göttingen, well known for his researches on vitamins, has been awarded the Goethe Medal for Art and Science on the occasion of his sixty-fifth birthday.

THE following appointments and promotions have recently been made in the Colonial Service: W. S. Luke, to be veterinary officer, Kenya; R. Johns, agricultural officer, Fiji, to be director of agriculture, Leeward Islands; C. W. Elliot, assistant conservator of forests, to be senior assistant conservator of forests, Kenya.

THE following awards have been made by the American Institute of Electrical Engineers: Edison Medal to Dr. J. B. Whitehead, professor of electrical engineering at the Johns Hopkins University; Alfred Nobel Prize for 1940–41 to Robert F. Hays, jun., of the research laboratories of the Sperry Gyroscope Company, for his paper entitled "Development of the Glow Switch".

THE immediate establishment of a Scientific Advisory Council for the war effort has been officially announced in Jerusalem. The Council will work in close co-operation with the Palestine Government. Dr. Judah L. Magnes, president of the Hebrew University, has been appointed president, and Prof. Farkas secretary of the Council, the membership of which will consist of representatives of the Hebrew University, the Technical High School at Haifa, and the Agricultural and Daniel Sieff Institutes at Rehovot.

ERRATUM. In NATURE of April 4, p. 383, "Linkage of Physico-Chemical Processes in Biological Systems' by Prof. E. J. Conway, equation 4 should read

$$2\ {}_K = C_Y + \sqrt{C^2{}_Y + 4\,(C'_K{}^2 + C'_K C'_N)}.$$

Behaviour of Lipoids in Human Serum

Filtered human serum gradually becomes turbid through the formation of a precipitate which is mainly lipoid. The presence of approximately 7 gm. of lipoid in 1 litre of human serum is shown by shaking with a mixture of ether and alcohol[1], when the protein is precipitated and the lipoid goes into solution. When ether alone is used, the protein is not precipitated, and negligible amounts of lipoid are contained in the ether extract. It has not hitherto been believed possible to remove lipoids in any quantity from serum by the use of ether alone.

If serum is shaken with ether and the mixture frozen below −25° C., on subsequent thawing a coloured ether layer forms on the surface containing large amounts of lipoid. Freezing at temperatures above −20° C. fails to produce lipoids in the ether layer, and freezing at temperatures down to −70° C. does not increase the amount in the extract. There is no apparent advantage in freezing for longer than is required to bring the bulk of frozen material uniformly to below −25° C. From 1 litre of human serum shaken with 300 ml. ether and frozen to −25° C., 3·5 gm. lipoid is obtained in the extract which forms on the surface after thawing in cold water and allowing to stand at room temperature for 6–8 hours. The underlying serum is siphoned off and will give another 0·85 gm. lipoid if shaken with 100 ml. ether and frozen. On repeating this, another 0·2 gm. lipoid is obtained, each successive extract containing approximately one quarter the lipoid of its predecessor.

A litre of serum which has been exhaustively extracted in this way gives a further 2·5 gm. lipoid on treatment with ether-alcohol. The serum separated at each stage is not clear to transmitted light but may be clarified by centrifuging. The final product contains 11 per cent dissolved ether, which can be removed in various ways. Freezing once more and thawing after removal of the ether causes the deposition of a gelatinous material of low solubility in cold water, and if this is removed by filtration in the cold through an ordinary filter paper the siphoned as well as the centrifuged product is perfectly clear at all temperatures and filters readily through a bacteria-retaining filter.

Electrophoresis photographs of human serum before and after the extraction show only one difference, namely, that the concentration of β-globulin has been reduced by the extraction. It follows that much of the apparent β-globulin of human serum is a lipoid-β-globulin complex so orientated that the protein determines the surface properties of the complex; or alternatively, that β-globulin itself is a compound of lipoid and a serum protein having surface properties different from those of its constituents. It is not possible to decide between these views on the evidence available, but it is at least clear that in the β-globulin fraction of human serum much lipoid is associated with a hydrophylic substance in such a way that it behaves atypically, that is, as a water-soluble and ether-insoluble material.

In the region of the eutectic temperature (−23° C.) of sodium chloride, serum becomes truly solid and, after thawing, the previously clear serum is cloudy. Similarly, serum which has been dried from the frozen state but not from the liquid state is reconstituted with water to form a milky suspension. This suggests that the association of lipoid with a stabilizing substance depends on the presence of liquid water and is destroyed by freezing. On subsequent thawing, unprotected lipoid is able to aggregate to visible particles or droplets. These, however, soon re-acquire the same stabilizer from solution, because the initial rate of aggregation is not maintained and the formed particles can be observed with the naked eye to migrate with the β-globulin boundary. The lipoid of these particles is also not extractable with ether unless accompanied by freezing.

After freezing and thawing, it must be assumed that a lipoid phase has been created in equilibrium with the aqueous phase, and if dissolved ether is present in the serum it will redistribute itself between the two. Lipoid aggregates containing dissolved ether rise to the surface and merge with the excess of ether there to form a solution of lipoid in ether. It may be suggested as an alternative to this that ether droplets containing dissolved lipoid are formed between the ice crystals on freezing, and owing to the low miscibility of ether in water these are able to rise to the surface carrying lipoid with them without re-solution of the ether taking place. This is contra-indicated by the observations that an extracted serum saturated with ether does not form an ether layer after freezing and thawing, and an unextracted serum saturated with ether but having no excess of it on the surface has the appearance after freezing and thawing of an emulsion and on standing a fatty layer collects at the surface.

The method of extraction has been used to clarify blood-grouping sera which had become cloudy, and these showed little or no reduction in agglutinin titre and remained clear in ether for nearly a year. Extracted human serum after drying from the frozen state is reconstituted with water to form a clear solution, and there is no evidence that the physical properties of the serum proteins have been affected by either process. For reasons not understood, most of the excess fat in a lipæmic serum is extractable with ether without freezing and the same has been found for the serum of nephrotics[2]. Details of the application of the method to citrate plasma are being published elsewhere.

Metabolic Products of 3 : 4-Benzpyrene

In 1936, Peacock[1] observed that animals receiving intravenous injections of 3 : 4-benzpyrene excreted in the bile an alkali-soluble product (*BPX*) possessing specific fluorescence bands which differed from those of the parent hydrocarbon. Subsequent investigations by Chalmers[2,3] demonstrated the existence of a similar phenolic derivative in the fæces, and this led to its isolation and purification. From recent crystallographic analysis[4], this metabolic product is considered to be a monohydroxy-benzpyrene.

In a study of the oxidation of benzpyrene by ascorbic acid *in vitro*, Warren[5] has found, in addition to the two known quinones (5 : 8- and 5 : 10-), a phenolic substance, soluble in alkali, giving a strong green fluorescence. In view of the apparent similarity of this synthetic phenol to the metabolic phenol *BPX*, and since *in vitro* the formation of the quinone preceded that of the phenol, Warren suggested that *BPX* might be a partially reduced quinone.

Previous work on the isolation of metabolic derivatives of benzpyrene has been hampered by the small yields of the products, due partly to their instability and partly to the small amounts produced. The latter was due, in the case of intravenous injection of benzpyrene, to the small amounts which can be injected by that route, and in the case of subcutaneous injection, to the slow rate of metabolic change under those conditions. From a study of the fate of benzpyrene in the animal body under different biological conditions[6], it was found, however, that the body metabolizes benzpyrene about fifteen times more rapidly when injected intraperitoneally than when injected subcutaneously. By taking advantage of this difference, it became possible to investigate the nature of the metabolic products of benzpyrene on a more extensive scale.

The fæces of rats which had previously been injected intraperitoneally with large amounts of benzpyrene were desiccated, ground to a fine powder, and continuously extracted with cold benzene. On purification of the extract by chromatography, etc., it was possible to isolate, in addition to the phenolic product *BPX*, a red crystalline substance, possessing similar properties to the synthetic red quinone (5 : 8-) obtained by the method of Vollmann *et al.*[7]. On reductive acetylation or methylation, strongly fluorescent compounds with distinctive spectra were obtained, those derived from the synthetic quinone being similar in type to those derived from the metabolic quinone. They both appeared to be very different, however, from the acetyl and methyl derivatives obtained directly from *BPX*. This is in keeping with the conclusion reached by Chalmers and Crowfoot[4] that *BPX* is a monohydroxybenzpyrene, since, on acetylation or methylation, such a substance would be expected to yield the corresponding mono-derivatives, in contrast to the di-derivatives which may be expected from the quinones.

On the other hand, on standing in air (and, more rapidly, by treatment with oxidizing agents), *BPX* tends to change partially into the red quinone, a reaction which rather suggests that it is a dihydroxybenzpyrene.

While further investigations are still in progress, the results so far available are not incompatible with the view that both a mono- and a di-hydroxybenzpyrene are produced in the body, the former being slowly converted into the latter, and the latter being rapidly converted into a quinone.

Effect of Chorionic Gonadotropin on the Pouch of the Marsupial *Trichosurus vulpecula*

THE pouch of the sexually mature, non-pregnant common Australian phalanger or possum (*Trichosurus vulpecula*) shows a marked reaction towards the administration of gonadotropic hormone obtained from human pregnancy urine. The immediate response during the period of administration is a decrease in the size of the pouch, but after about three injections of 200–500 I.U., the pouch expands *markedly within a few days after the final injection.* The increase in size in the caudal direction extends down to the pubis; in the lateral direction the cavity may expand over the whole of the lower abdominal wall. In such cases the extended pouch would be capable of housing a large pouch young of about one eighth of the body-weight of the mother. With the expansion of the pouch, mammary glands and nipples also increase in size and the interior of the pouch becomes very moist due to the secretion of a fluid which at first is colourless and then turns brown. This enlarged pouch persists for about a week, then slow involution takes place extending over several weeks.

In comparing the action of œstrogens[1] and progesterone[2] with that of gonadotropin, it may be pointed out that œstrogens bring on a contraction, and progesterone, after a slight preliminary expansion, a relaxation and eversion, while gonadotropin brings *on an enlargement of the pouch. It therefore appears* that the same hormones may control the activities of the pouch and of the eutherian uterus.

Heterothallism and Reproduction in Fungi

WE are grateful for the clear genetical interpretation of heterothallism given by Dr. K. Mather[1], and may perhaps be allowed to carry his conclusions regarding reproduction in fungi a step further. We have been thinking on these lines for some time, and in a joint discussion held by Sections D and K at a meeting of the British Association in 1937, the suggestion put forward by one of us[2], that the heterothallism of some fungi might be compared with the incompatibility of some angiosperms, was not received sympathetically by the mycologists.

The evolution of heterothallism in fungi, a phenomenon not necessarily the outcome of sex, but possibly an independent and alternative process, has brought with it the problem of the bringing together of opposite strains: a problem intensified by the non-motile 'gamete' of the *majority of fungi, and o*[illegible] peculiar importance in parasitic forms. Various mechanisms have been evolved which achieve this end, and it is in the interpretation and naming of these mechanisms that confusion has arisen between heterothallism and sex. The process whereby the strains are brought together has been spoken of as the actual sexual process, whereas in many instances it no more represents a sexual process than does the carrying of a pollen grain to the stigma of an angiosperm. In many forms the strains are brought together by the dispersal of asexual spores such as oidia and papulospores which multiply the individuals of one or other strain and serve to disperse them so that intermingling will be more assured. When the appropriate strains meet, one of two things may happen: (*a*) sexual organs are formed as soon as contact is established (Mucor, Dictyuchus) or (*b*) mycelial fusions occur in vegetative hyphæ mingling the protoplasm and associating the nuclei of the two strains, which fusions may be between two hyphæ, or two spores, or hypha and spore. A further development of this last type of fusion might give rise to a hypha specialized to catch the spore. Such a mechanism does not convert the spore into a gamete or make it necessary to assume that in *Pleurage anserina*[3,4], for example, we have a trichogyne catching a spermatium, particularly as in *Neurospora tetrasperma*[5] the trichogyne may fuse with ordinary vegetative hyphæ.

The analogy of the transference of pollen in seed plants and the transference of oidia in the higher fungi becomes very close when the 'devices' of colour, scent, and nectar are found in the pycnidium of rusts as well as in the flower, and when insects are found to serve as the agents of transference in both.

These vegetative fusions give rise to the peculiar condition found in numerous Basidiomycetes and Ascomycetes, where two different kinds of nucleus are found within a thallus, and nuclear fusion is delayed. Here there is no need of sexual organs and it is possible to argue either that sexual organs have been lost or that sexual organs have never arisen in this line of evolution. The plant secures nuclear association without them. The recognition in some Ascomycetes of an oogonium without antheridium can be used as evidence in support of the former view. On this argument antheridia have disappeared first and the oogonium has been retained either (*a*) as a sorting-out place of the pairs of nuclei or (*b*) as a place of fusion. The assumption that this 'oogonium' is a normally functioning sexual organ may explain the theories of double fusion and brachymeiosis in Ascomycetes—a phenomenon universally unacceptable to geneticists. The evolution of the clamp connexion renders unnecessary the presence of an oogonium even as a sorting-out place for the nuclei, and it is significant that in forms with conjugate division of dicaryons (even though there be no clamp connexions) there appear to be no sexual organs. They may have been lost but possibly they never existed.

External Genitalia of the Diptera

IN medical and veterinary entomology specific and generic determination of flies is dependent upon the structure of the genital apparatus. There is no recognized standard for naming the modified terminal segments and appendages (terminalia) of the abdomen in the Cyclorrhapha. Morphologists have found no conclusive evidence to settle the nature of, nor have taxonomists managed to agree upon the naming of, these sclerites and other parts concerned. Nevertheless there are four papers that have, between them, covered the groundwork required to solve this problem. Together they make an entirely new approach and I have co-ordinated the data. The following conclusions that are drawn from this study are surprising, but logical.

(1) The normal Nematocera have ten observed abdominal segments, the tenth being the proctiger, which includes the anal papilla. The ninth segment incorporated the ædeagus, and these two together form the hypopygium. The ten abdominal segments lie in a rectilinear series with the anal papilla, lying in a plane above that of the ædeagus which points posteriorly, that is, away from the head of the fly.

(2) The first change to take place is in the hypopygium, which rotates on its longitudinal axis through 180°, becoming inverted as in mosquitoes. Here the ædeagus lies in a plane above that of the anal papilla, and retains its character of pointing posteriorly.

(3) The terminal segments of the abdomen, usually from the sixth onwards, change their line of direction to a curvilinear series, so that the hypopygium is turned to point laterally, dorsally and ventrally, and hence the ædeagus no longer points posteriorly, numerous examples of which are found in the Empididæ and Dolichopodidæ.

For the purpose of the present discussion, it is necessary only to consider the case where the abdomen curves through a half circle in a lateral direction, so as to have the ædeagus pointing anteriorly, that is, towards the head of the fly as in Syrphidæ.

(4) In the Orthorrhapha, every fly that has the anteriorly directed ædeagus always has a simple curvilinear form of the abdomen, so far as known. The hypopygium here is never inverted, so the eighth and ninth tergites are adjacent one to the other.

In the Cyclorrhapha, on the contrary, the hypopygium is invariably inverted, the ninth tergite always being adjacent to the eighth sternite. Metcalf has given the evidence for Syrphidæ very clearly, but he marks the eighth sternite as being the ninth urite, having had doubts about its nature.

The course of the spiracles and the loop of the genital tract over the alimentary canal are found to be common to all the Cyclorrhapha, showing that fundamentally the terminalia of the Syrphoidea and those of the Muscoidea are based upon common ground.

(5) By following this evidence logically, it can be seen that the apical segments of the Muscoidea must have their eighth and ninth sternites on the dorsal surface, comparable to that already shown for Syrphoidea by Metcalf. The ædeagus moves forwards to lie under the eighth sternite in both cases. The so-called 'cerci', that is, the styles of Metcalf, are derived from lobes of the ninth tergite which is, itself, retained in vestige by the Syrphoidea, but is obsolete in Muscoidea. Similar lobes are derived

from the eighth sternite and sometimes from the seventh sternite too, the *Calliphora sternalis*-group being an example.

This sequence of changes that takes place in the terminalia was seen when studying the four following papers :

(*a*) C. L. Metcalf, *Ann. Ent. Soc. America*, 14, 169–214 (1921), who discusses "the genitalia of male Syrphidæ ; their morphology, with special reference to their taxonomic significance". Metcalf adds an extra segment to the base of the abdomen and produces a numbering of segmentation that is not followed by other authors. Reduction of his numerals by one brings the numbering to that of the above notes.

(*b*) G. C. Lamb, *Proc. Roy. Soc. London*, B, 94, 1–11 (1922), who uses the order in his account of "the geometry of insect pairing". Lamb overlooked the fact that the ædeagus is inverted on Syrphidæ, so his ideas on the terminalia are in need of adjustment. The correlation between the ædeagus and vagina is not direct but inverse, as Richards found.

(*c*) H. J. Feuerborn, *Zool. Anz.*, 189 (1922), who discusses "das Hypopygium inversum und circumversum". Feuerborn has overlooked the fact that the "circumversum" form of hypopygium can equally be gained by combining his "inversum" form with the curvilinear form of terminalia described by Metcalf and by Lamb. The hypopygium does not turn through 360° relative to the eighth segment as Feuerborn states, but is derived directly from the Syrphid type as Lamb suggests.

(*d*) O. W. Richards, *Biol. Rev.*, 2, 322–328 (1927), who discusses "the mechanical relations of the male and female genitalia" when reviewing "sexual selection and allied problems in insects". Richards reaches several conclusions that cannot be retained. The twist of the hypopygium is restricted to one way only throughout the Brachycera, namely from left to right, and the curvilinear development in Cyclorrhapha takes the same direction. Three segments each take 60° twists, not two at 90° each which Richards suggests.

The treatment of the so-called 'cerci' of authors, as reviewed in the above notes, is in alinement with my manuscript "The Copulation and the Terminal Segments of Diptera" ; typescript copies (about 10 pages and 25 text figures) will be made available to authors interested, on application being made to me personally, for with present printing restrictions it is not likely that the paper will be printed for many years.

Colour Measurement

MR. J. W. PERRY[1] quotes previous statements by me in contradiction of the view expressed by T. Smith, R. Donaldson and myself[2] that the C.I.E. standard-observer tables are not restricted in their application to a specified field size or other observing conditions.

The apparent contradiction arises from failure to appreciate the essential difference between measurement of the quantities occurring in the psychophysical relations which determine an observer's personal experience of colour and brightness matching, and measurement of quantities of the kind defined by the C.I.E. tables. It is to the former class of measurements that the statements in question apply ; measurement in terms of a public standard, conventionally accepted for technical purposes, was not within the scope of the paper quoted by Perry.

Adequate discussion of the points at issue within the limits of a letter is impracticable, and inadequate discussion would only leave room for further controversy. I propose, therefore, to prepare a statement for submission to the Physical Society Colour Group, where a full discussion may be possible.

Meanwhile it is sufficient to say that there is nothing in Mr. Perry's letter which appears to us to warrant modification of the views which we have expressed in these columns.

First Publication of the Geological Society

IT is interesting to learn[1] that an original copy of the "Geological Inquiries", said to be the first publication of the Geological Society, has been discovered in the library of the Sedgwick Museum. When Woodward stated that "No records appear to have been preserved of the printed geological inquiries that were circulated among the members", he was evidently unaware that this pamphlet had been reprinted, apparently verbatim, in A. Tilloch's *Philosophical Magazine*, 49, 421–429 (1817). The queries were also included in full (unnumbered, and without the introduction) by Thomas Walford, F.A.S., F.L.S., in his "The Scientific Tourist through England, Wales and Scotland", London, 1818, 2 vols., 12mo. (vol. 1, pp. 50–55), a copy of which is in the library of the Geological Society. It may perhaps be of interest to add that the latter publication also includes a folding plate, "Geological Table of British Organised Fossils . . . with reference to Mr. Smith's Geological Maps". This is almost identical with Smith's well-known table which appeared in the later issues of the memoir accompanying his map and was also published separately.

One would like to know if the pamphlet is dated, or bears any evidence to show that it was actually published in 1808, or before 1811 (the year in which the first volume of *Transactions of the Geological Society* appeared). It seems strange that it should be included in a monthly scientific journal, without comment, nine years after it had been circulated to the fellows of the Society. It would be most interesting if Dr. Hawkes could provide evidence, either from the pamphlet itself or from the early minute books of the Society, to confirm the date of publication.

NEW ZEALAND EARTHQUAKES DURING 1940

An interesting and informative account of New Zealand earthquakes and seismology during 1940 is given in Bull. No. R–26, of the Dominion Observatory, Wellington, published in the annual report of the Department of Scientific and Industrial Research, 1940–41 (New Zealand).

Data for the study of earthquakes are obtained locally in New Zealand from instrumental records of three main types and from personal experiences as follows: (1) from teleseismic instruments of varying sensitivity installed at Arapuni, Wellington, Christchurch and Chatham Islands; (2) from local strong-motion recorders, mostly Jagger seismographs, installed at Rotorua, Hastings, Bunnythorpe, Takaka, Greymouth and Monowai; (3) from sensitive local recorders of Wood-Anderson design situated at Tuai, New Plymouth, Wellington and Christchurch; (4) from reports of felt earthquakes from non-instrumental reporting stations established with the co-operation of the Post and Telegraph Department.

Periodical reports of felt earthquakes are also received from Dr. C. E. Fox in the Solomon Islands, and also from the Kermedecs. During 1940, 90 earthquakes were reported felt in the North Island, 40 in the South Island, 10 in both islands and 120 over the whole of New Zealand. In the North Island, maximum numbers were in March, July and August, in South Island in February, and in the whole of New Zealand in July.

The ten most important earthquakes occurred: (1) January 12 at 00h. 05·4m. N.Z.M.T., with maximum intensity 5 on the Rossi-Forel scale, felt extensively from Hawera to Akaroa, with maximum at Wanganui and Blenheim; (2) February 26 at 17h. 46·6m. with intensity between 6 and 7, felt throughout Hawke's Bay, with maximum at Hastings; also felt at Taihape and Wanganui; (3) March 20 at 02h. 23·5m. with intensity 7, felt in most eastern districts of North Island as far south as Dannevirke, with maximum in North Hawke's Bay; also felt in parts of Wanganui and Manawatu districts; (4) April 19 at 18h. 11·5m. with intensity 6, felt widely in North Island south of Napier, Taihape and Hawera, with maximum at Dannevirke (possibly two shocks); (5) July 10 at 05h. 28·1m. with intensity 6, felt at Whakatane; (6) July 23 at 01h. 01·5m. with intensity 4, felt in western areas of North Island from New Plymouth to Wellington, and at isolated points in northern part of South Island; (7) August 2 at 04h. 28·8m. with intensity 6, felt in Gisborne region and parts of northern Hawke's Bay; (8) August 2 at 04h. 37·4m. with intensity 6, felt in Gisborne and parts of northern Hawke's Bay; (9) October 7 at 12h. 55·65m. with intensity between 6 and 7, felt widely in North Island, except Auckland Peninsula; also at isolated places in South Island to Banks Peninsula; maximum in region between Opotiki and Hawke's Bay; (10) October 22 at 06h. 16·9m. with intensity 6, felt about Cook Strait.

From all the available information it will be seen, that the main features of the activity may be summarized as: (1) Two strong shocks centred in the Gisborne coastal regions on August 2. (2) Fairly continuous activity beneath the volcanic zone extending from near White Island to the region south-west of Lake Taupo from March onwards, with a particularly strong shock on October 7. This shock had a focal depth of 160–170 km. and was widely felt. Shocks at intervals centred in the Taumarunui region are considered to be part of the activity connected with the volcanic zone. (3) Activity in Hawke's Bay region reached a climax with the shock on March 20. It was followed by a swarm of minor aftershocks recorded at Tuai, most of which were too weak to be felt. Following this disturbance there was a steady decline in the intensity and frequency of the shocks, and between August and the end of the year only one shock was definitely located in Hawke's Bay. (4) Occasional minor activity centred in north-eastern Taranaki, probably associated with the shocks in the Taumarunui region. (5) Fairly frequent slight or moderate shocks in the Wanganui-Rangitikei region, many of which were centred in the Wanganui Bight. (6) Rather frequent shocks in the Wairarapa, Wellington, Marlborough and West Nelson regions during the latter half of the year, none of which exceeded Rossi-Forel 5. The coincidence of renewed activity in all these regions about June points to some common cause affecting shock activity in the whole area. (7) Activity in the submarine region east and north-east of the North Island in July–August, and again from October to December.

During 1940, tests were carried out near Greymouth and at Monowai with Milne-Shaw and Wood-Anderson seismographs. Both places were found unsuitable for the Milne-Shaw but suitable for the Wood-Anderson. The co-operation of the Public Works Department has been sought with the view of establishing a Wood-Anderson near Greymouth. Tilt recording has been carried on continuously at Wellington with the aid of the Ishimoto tiltometer and the Milne-Shaw seismograph. The Lands and Survey Department has furnished information on levels taken across geological faults at various points in the Wellington District during the period 1930–40. A study of these level readings, together with seismic data, indicates that certain level changes may have been associated with definite seismic disturbances, though more frequent level readings will be required to confirm this. Since 1936, systematic observations of the north and south meridian marks have been made with the transit instrument. Relative horizontal movements of any one of these points would be revealed by the observations. No appreciable displacements have so far been detected.

CHEMICAL ASPECTS OF TUBERCULOSIS

Dr. Florence B. Seibert, associate professor of physiological chemistry at the Henry Phipps Institute, Philadelphia, read a paper during the fiftieth anniversary celebrations at the University of Chicago in September last describing the results of recent chemical studies of the bacillus of tuberculosis.

Dr. Seibert stated that it is now possible to separate the polysaccharides and nucleic acid from the protein of the bacillus, and this has led to the discovery that there are several types of proteins derived from the tubercle bacillus, varying in potency. She also posed the new problem of whether the 'fast component', one of the tuberculin protein types, may be related to an unidentified 'extra' component in the blood serum of persons sensitized to tuberculosis.

This 'extra' substance, with a mobility slightly greater than that of the albumin normally present in the blood serum, is found to have exactly the same rate of mobility as the 'fast component' of the tuberculin protein.

There is no longer any doubt, Dr. Seibert said, but that the protein fraction is of paramount importance in many reactions accompanying the disease. The whole question of hypersensitivity and allergy is interlinked with sensitization to the protein. For this reason much effort has been spent in attempts to isolate the protein in pure form. This work has been carried on for many years, first at the University of Chicago and during the past nine years at the Henry Phipps Institute, with grants from the Medical Research Committee of the National Tuberculosis Association.

Each succeeding stage in the purification, however, has brought with it the realization of its great complexity. Through the use of some of the modern physico-chemical methods, especially the ultracentrifuge and the Tiselius electrophoresis apparatus, it has been possible to formulate a definite picture of the complex composition of the tuberculin protein and to obtain some leads for further purification.

The free polysaccharide and nucleic acid have been shown not to be responsible for the biological reactions so characteristic of tuberculin. However, they form very definite combinations with the protein, some of which dissociate only at certain hydrogen ion concentrations. For example, it was shown in a heated fraction that nucleic acid and protein travelled in electrophoresis as a single component at hydrogen ion concentrations more acid than *p*H 5·0, whereas on the alkaline side they existed as two separate components with very different mobilities. This protein can exist in various molecular sizes and shapes. In general, larger, less denatured, and more spherical protein molecules in the bacillus are more dangerous than smaller, more denatured, and more elongated molecules. Among the effects produced are the stimulation of the body to produce antibodies and the heightening of susceptibility to later exposures to the disease.

The tuberculin protein has a doubly dangerous effect because when introduced into a body never previously infected, it proves more poisonous than most ordinary proteins, and in addition, infection causes a heightened sensitivity to this protein when it is formed in the disease in later exposures, rather than immunity. For example, 100–150 mgm., given intraperitoneally, will kill a normal guinea-pig. Ten times this amount of a protein from another acid-fast bacillus, the timothy grass bacillus, was not lethal. The toxicity of the tuberculin protein is increased about a hundredfold in the tuberculous animal, the sensitivity of which has been greatly enhanced by the infection. There seems to be no evidence that the antibody which can be demonstrated in the blood stream is directly associated with immunity. In fact, animals highly sensitized to the protein did not possess an immunity to infection. They showed a lessened immunity.

Furthermore, there is no evidence for a bactericidal effect by the blood serums of highly immunized animals on the tubercle bacillus *in vitro*. On the other hand, there is evidence from the work of Dr. Max B. Lurie (also of the Phipps Institute) that the body fluids of tuberculous animals are bacteriostatic in experiments with living animals.

Analysis and sorting out of the molecule comprising the tubercle bacillus is made extremely difficult by the presence, and even association, of the polysaccharide and nucleic acid with the protein. However, with the development of a satisfactory method for removing these two impurities without harming the protein, a very active protein can now be isolated. The potency can be carefully standardized, and a quantity of such a preparation for general standardization purposes has been prepared. But it is still obvious that more research must be done in order to be able to separate the different kinds of protein molecules from each other and then to develop satisfactory methods for producing them at will and in desired quantities.

PALÆOLITHS FROM THE WORTHING ARCHÆOLOGICAL AREA

By F. W. H. Migeod

PALÆOLITHIC implements of early types have been found recently by two local residents in the Worthing archæological area. One collection was made on the Worthing shore by Mr. Barclay Wills. His work came to an end when access to the beach was prohibited in the early days of the War. Mr. R. K. Stevens was able to begin his at Angmering-on-Sea, about five miles to the westward, when grassland was ploughed up for cultivation. Most of his finds were on the surface, a few only, but they of large size, coming from ditches. I had practically completed a detailed description of Mr. Stevens's finds before Mr. Wills's came to my notice. As a result the joint collection here briefly reviewed consists of a hundred of Mr. Stevens's flints and thirty-three of Mr. Wills's.

The cultures were mainly similar. A glance at them shows the great variety of uses to which the flints were adapted. The flaking is bold, and minor chipping in general rare. Their time-range is wide. Some seem to be of eolithic type. The majority, however, may be classed as Chellean. Three may be Clactonian, one Acheulean and one Mousterian. There are also some intrusions, which is only to be expected from the proximity of the neolithic flint mining industry on the nearby downs. Although there are time distinctions, the absence of a clear stratification at Angmering-on-Sea renders precision in this respect out of the question.

The technique of the main body of implements from both sites is in the first instance cleaving a piece off the flint block with a single blow, thus producing a smooth lower surface. The outer and crustal surface is then flaked as required. The smooth under-surface is retained whatever may be the nature of the resulting implement. What sort of implement will emerge depends on how the maker views the possibilities of the fragment he proposes to work on. This factor disappeared when in the later stone age the core of the flint nodule was principally used for implement making.

A wide range of implements has thus emerged, among which may be identified a variety of series as hand picks, hand axes (single and double), hand choppers, knives and saws, borers, spear heads, (?) sickles, side scrapers, hammer stones, planes, gravers, spheres (somewhat angular), hooks, and miscellaneous small cutting flakes and pygmies. At Angmering-on-Sea intrusions include a sandstone axe head and a banded-chert implement, possibly an adze, with a cutting edge at one end and a point at the other; also some few neolithic implements.

The first series I shall describe consists of eight nodule implements, seven from Angmering-on-Sea and one from Worthing. These are similar to those found by Dr. E. Hugh Kitchin in the Bournemouth area. I use the name he gave to them. These are flints with the crust left, except at points where flaked. He considered his finds covered a wide range of time; and this seems to be the case here too, as some are patinated and others not. The few implements I have doubtfully called eolithic fall into this series.

The Clactonian flaked cores are from Angmering-on-Sea and have a rich patination.

An interesting series for which I selected a dozen specimens out of a larger number consists of what I have called 'worm-eaten' flints. They are deeply indented and the material is most refractory. Nevertheless implements were produced in the same technique as in the main body of the collection. The difficulties of excrescences and deep indentations were successfully overcome, especially as regards the latter, by ignoring their presence. The result is in some cases a veritable *tour de force*. There are what are intended for spear heads, (?) an adze, beaked implements of rostro-carinate type, a borer, a side-chopper, and axe head, (?) a plane, and a double-tailed implement as if for scraping down a pole to size. All this series comes from Angmering-on-Sea.

Another feature from the same locality, where numerous finds are of mint-like sharpness, is a series of crude implements, many of them picks, which have suffered from abrasion. They must for that reason be assigned a position among the oldest. The sharp edges of the facets are worn down, not necessarily on all sides. Whether the cause was moving ice requires further consideration.

As to the various classes of implements, there is an axe weighing 5½ lb., and measuring 194 mm. × 150 mm. × 70 mm. It is a natural block thinning towards what was adapted as a broad cutting edge. At the butt end a vertical cutting edge was contrived. It might have been used for killing elephants or other large animals. The knives and saws consist of a flint with a flat cleavage surface on one side, a rougher one on the opposite side, and crust left on the back. In one specimen there is clearly right and left chipping to make the saw edge. A fine and unique specimen is from the Worthing shore, measuring 208 mm. × 57 mm. × 30 mm. There is a gradually thickening blade which is about three fifths of the total length and 40 mm. wide with two edges. The handle widens abruptly, and there is no crust. A claw-shaped knife from Angmering-on-Sea, with flanged sides, measuring 95 mm. × 72 mm. × 21 mm. is also an interesting specimen.

The borers are of three kinds. A common form has a broad flattened point projecting from the middle of a long edge. Judging by the varying patination, this kind had a long time-range. The points of others are rectangular or prismatic, and at Angmering-on-Sea are found a number of water-rolled beach flints hacked to the latter specification, their altered texture being helpful in this respect. Other points are more suitable for boring small holes.

Seven spear heads show some waisting near the base. One is especially outstanding in this respect. They, too, have in most cases one flat surface. In two or three flints, crescentic cutting edges may suggest their being sickles. The planes are of various shapes, specimens with a 'two-humped camel back' being among them. The plane surface is in some cases of a perfect smoothness. The 'steep-nosed' type of plane is common. Two hooks from Angmering-on-Sea, of thin tabular flint, the larger 118 mm. × 35 mm. × 20 mm. would suggest use as harpoons were they sharper.

The range in size of these implements is considerable, extending from the 5½ lb. axe, some hand picks being nearly as large, down to small borers and knife-like flakes, and to minute flint points half an inch long which might have served as gravers. A further feature is that some of the implements have a dual use, some of the knives or saws having a point as well as a cutting edge. As to the Worthing shore flints, they are commonly stained a blue-black, while a few are ochreous, which may only be on one side. Some have serpulæ and coralline growths on them. From the known history of the shore they cannot have been very many centuries under water, and that only at high or half tide. Mr. Wills considered he had found two hearths, around which he made most of his finds. He also considered knapping had been done on the spot. There were difficulties in examining a particular spot. The shifting sand on the chalk rock would for a few days facilitate the work, and then the site might be buried even for years.

In going over the many hundreds of flints brought in by Mr. Stevens, I was fortunate in finding two implements which had on them secondary growth, a comparatively rare occurrence. As the growth was on the sharp edge produced by flaking, a time value is forthcoming. I had not long before found a natural flint in a newly cut trench on a ridge near Cissbury also with such a growth on it, and all three specimens are now in the British Museum (Natural History).

Several industries may be tentatively identified from these collections. There was especially hunting and the preparation of skins. Agriculture cannot be entirely ruled out. Woodworking is also indicated, as there are stones suitable for the sawing and scraping of sticks and boring the wood. These early folk presumably lived in houses of some kind, a supposition all the more tenable seeing that there were no caves or other natural protection for them. The grouping of the flints would further seem to indicate village life.

Connexion with the flint industry on the downs is slight, as the industry up there is mainly neolithic, though the implements be not ground or polished. The mining operations on the chalk downs in search of good flints, which possibly did not begin before neolithic times, were elaborate. Shafts were sunk and galleries driven. The core of the flint nodule was wanted as opposed to the outer part used by the early coastal plain inhabitants. These latter could occupy the plain during the glacial period or periods when the hill tops were under ice or snow. In later ages when the névé disappeared the hills were preferred for living on to the damp and forested lowlands.

The discoveries of Mr. Stevens and Mr. Wills are of great interest. It is not possible in a short article to enter into more detail. They will, however, serve to shed a new light into the darkness enveloping palæolithic man on the Sussex coastal plain.

FORTHCOMING EVENTS

Saturday, April 18

BRITISH INSTITUTION OF RADIO ENGINEERS (at the Federation of British Industries, 21 Tothill Street, London, S.W.1), at 3 p.m.—Mr. P. P. Eckersley: "Future Developments in Communication Technique".

Monday, April 20

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. E. Ambrose: "The Distribution of Electricity" (Cantor Lecture, 1). (Subsequent Lectures on April 27 and May 4.)

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5 p.m.—Major the Hon. R. A. B. Hamilton: "Six Weeks in Shabwa".

Tuesday, April 21

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. M. G. Kendall: "The Future of Statistics".

Wednesday, April 22

INSTITUTE OF PHYSICS (LONDON AND HOME COUNTIES' BRANCH) (JOINT MEETING WITH THE GEOLOGICAL SOCIETY OF LONDON) (in the Geological Society's Rooms, Burlington House, Piccadilly, London, W.1), at 3 p.m.—"Some Aspects of Geophysical Survey". Dr. J. M. Bruckshaw: "Some Factors limiting Geophysical Prospecting"; Dr. A. F. Hallimond: "Magnetic Explorations of the Geological Survey"; Prof. V. C. Illing: "Geophysics Applied to Oil Geology"; Dr. D. T. Germain-Jones: "Seismic Refraction Technique"; Prof. O. T. Jones, F.R.S.: "The Relation of Geophysics to Geology".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 4.30 p.m.—Major H. C. Gunton: "Report on the Phenological Observations in the British Isles from December 1940 to November 1941"; Dr. Maung Po E: "The Foreshadowing of the Rainfall of Burma".

Thursday, April 23

BRITISH SOCIETY FOR INTERNATIONAL BIBLIOGRAPHY (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 2.15 p.m.—Annual General Meeting; Presidential Address; Symposium with demonstrations on the Photographic Reproduction of Documents.

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1) at 4.30 p.m.—Sir Arthur Keith, F.R.S., will exhibit Cranial Casts of South African Anthropoids, discovered by Dr. R. Broom, F.R.S., possessing Characters hitherto regarded as Human. Mr. R. E. Smith and Prof. C. N. Hinshelwood, F.R.S.: "The Detection and Inhibition of Free Radical Chain Reactions". Mr. W. S. Bullough: "The Starling and Foot-and-Mouth Disease".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Dr. O. E. Buckley: "The Future of Transoceanic Telephony" (Thirty-third Kelvin Lecture).

Friday, April 24

ROYAL SOCIETY OF ARTS (INDIA AND BURMA SECTION) (at John Adam Street, London, Adelphi, W.C.2), at 1.45 p.m.—Sir Hassan Suhrawardy: "The Development of Medical Education in India".

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Prof. C. H. Lander: "A Review of Recent Progress in Heat Transfer" (to be followed by a Discussion).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SENIOR ENGINEERING ASSISTANT TO THE STAFFORDSHIRE POTTERIES WATER BOARD—Mr. P. Wilkinson, Engineer's Offices, Albion Street, Hanley, Stoke-on-Trent (endorsed 'Senior Engineering Assistant') (April 22).

LECTURER IN THE DEPARTMENT OF MATHEMATICS—The Registrar, University College of Swansea, Singleton Park, Swansea (April 22).

PRINCIPAL of the Durham Road Senior Technical and Commercial Evening Institute and Day Technical Classes—The Director of Education, Education Offices, Prince Consort Road S., Gateshead 8 (April 24).

ASSISTANT MASTER TO TEACH MATHEMATICS AND ELEMENTARY SCIENCE in the Junior Technical School—The Secretary for Education, Tudor House, Friar Street, Worcester (April 25).

UNIVERSITY CHAIR OF OIL ENGINEERING AND REFINING (PETROLEUM TECHNOLOGY)—The Secretary, The University, Edmund Street, Birmingham 3 (May 9).

UNIVERSITY READERSHIP IN ORGANIC CHEMISTRY tenable at London (R.F.H.) School of Medicine for Women—The Academic Registrar, University of London, Richmond, Surrey (May 12).

UNIVERSITY CHAIR OF RADIOLOGY (THERAPEUTIC) tenable at Middlesex Hospital Medical School—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (May 26).

SECOND ASSISTANT PORT ENGINEER by the Iraq Government for the Basrah Port Directorate—The Central Register, Ministry of Labour and National Service, Queen Anne's Chambers, Tothill Street, London, S.W.1 (quoting E426).

EDUCATION FOR CULTURE AND CITIZENSHIP

THERE has been of late much adverse criticism of the way in which the sciences are taught in schools and colleges of Great Britain. This criticism takes a variety of forms. It is asserted that the work is too specialized, that it is too academic, or that too much attention is devoted to the teaching of technique. The chorus of complaint may indicate that there is something wrong, but it does not follow that the fault is entirely with the teachers ; it is just as likely to lie with those who complain, and the danger is that their specious criticisms may influence the teaching in a wrong direction. If biological teaching, for example, is centred around man, as many educationists would have it, that teaching is bound to become subjective, and trouble is certain to arise (see p. 457). It is essential that the objective attitude should be cultivated and developed as fully as possible in all branches of science teaching.

Furthermore, some schools have taken up biology, for example, because it seemed to be becoming 'fashionable', and the school must be in the swim. An economic motive arises from the increase in the number of entrants into the medical profession, and from an erroneous idea that there is a large number of research posts in biology. It seems then that this subject has got into the curriculum partly upon sufferance and partly because a demand for it has arisen in the public mind. It is only here and there that it is taught as a worthy subject which provides appropriate training for a certain type of mind (a type more common than is often appreciated), and there is not as yet a sufficient realization that the training is as valuable as that afforded by a study of the so-called more exact sciences.

All sound teaching of the science subjects rests on several things, but above all on careful and accurate observation. Such careful and accurate observation is not within the capacity of an untrained observer ; the students have to be taught to observe. Critical observation breeds a critical habit of mind and a capacity for using the information obtained by the observation. It provokes and promotes thought. A person trained in the habit of observation applies that habit to all with which he has to deal. Training in observation and in the habit of mind it engenders is one great contribution which science has to make to education.

To train students in accurate observation is a severe test of the teacher's ability. Many students, rightly and naturally, take much pleasure in making preparations, in analysis, in dissection and in compiling books of drawings, but these things by themselves are not science. From the over-emphasis of technique and the memorizing of too many facts comes the widespread and erroneous opinion among those who know little and care less about science that skill in technique and the knowledge of a long list of forbidding terms make up the whole of science. It should be recognized that these are but means to the end, which is training in the art of close and accurate observation. There is a value also in the confidence the student gets from his ability to do something in a workman-like manner. Sound work in the sciences acts as a protection against over-hasty generalizations. The diversity which is one of the charms of plants and animals, for example, stimulates curiosity and keeps the mind alert. It makes the observer watchful, and it encourages a habit of mind which demands evidence rather than unsupported statements.

Practical work is important, but it must be kept in correct perspective. It must be within the capacities of the students; for example, in biological work it will be mainly morphological, with a functional bias. Elaborately developed cytology and physiology do not provide suitable practical exercises, and consequently information has to be got from books rather than from personal experience.

There are special difficulties in teaching biology to town-bred children, though this is not true of all the sciences. While the town dweller is denied full access to much of scientific interest, yet he often has access to museums, zoos, gardens, works and factories which can serve him well, and could serve him better if close co-operation were established between controlling authorities. The cinema is becoming a more and more efficient instrument of instruction, and it can and should be used to supply something at least to compensate the disadvantages inevitably suffered by the student living in a large town. But the films must not take the place of direct work.

It is probably true that the greatest hindrance to science teaching is the examination system. Rightly or wrongly, teachers may consider it their main task to get their students through examinations, and if they do not themselves think so, that point of view may be imposed on them either by the administration or by public opinion working through the administration. The objective becomes the piling up of examination successes, and the bigger and more impressive the pile, the better the work of the school and of the teacher is supposed to be. All that being so, it is not remarkable that the schools may aim, not merely at getting as many examination successes as possible, but may seek to acquire additional merit by pushing as many pupils as possible through the stiffest and showiest examinations available. The subjects certainly suffer, and there is more than a suspicion that the welfare of the students may be sacrificed to the chance of academic successes for the school.

All this reacts on the mentality of the students, who get more and more the idea that the aim of their schooling is to enable them to pass examinations; the more stupid, and a very few with an abnormal dose of common sense may escape this. To pass the more showy examinations, specialization is thought to be needed, and this thought is gaining ground to such an extent that there is even talk of introducing research into the schools, a charming illustration of a tendency not unknown in educational schemes, that of starting a building with the roof and working downwards. Following this supposed need for specialization, we find harassed teachers attending scientific meetings, hastily grabbing up such crumbs as they can snatch, and decanting the fragmented results of recent research on their unfortunate students in the hope that this will scrape together a few more marks.

It seems clear that we must have some form of school-leaving examination to provide a test of how the machine is working, and to give an aim, for unless there is an objective the work is likely to be diffuse and pointless. But the present custom of having two such examinations, one at a lower and one at a higher level, is to be deplored. One examination should be sufficient, and it should be organized so as to provide an adequate test of the general education of candidates aged between fifteen and sixteen years. If the pupils stay in the school beyond the age of sixteen, they should not then be pushed on to specialized work; that work should be done in technical institutions or in universities.

Older students who have given evidence of possessing satisfactory general competence should be allowed, during the later part of their school life, a temporary respite from examinations, and should be able for at least a year to pursue with some freedom whatever line of learning attracts them. That liberty, following several years of preparation for the School Certificate examination, would loosen up their mental joints and enable them, before they are caught up into industry or into a period of specialized training for a profession, to look around somewhat and perceive that scholarship is something more than textbooks and formal lessons.

During this 'sabbatical year' the student might look aside somewhat from those subjects in which he may afterwards specialize. This would be the opportunity for the future student of science to give some time to arts subjects, and for the future arts student to profit from instruction in science; both groups would benefit from some mathematics at this stage. At present, the student on the science side may be stultified by the repetition of the same kind of chemistry and physics year after year during his school life. He could profit well from instruction in the use of English during this period of recuperation (see p. 454). For some reason the writing of essays now seems to be taboo, and the study of English literature does not seem to be favoured. All this may explain the frequent and shocking illiteracy of students entering the universities. Let the student in this year of his freedom dip, as he feels moved, into the glories of English literature, but let there be no set books, no commentaries and no annotated editions.

If, for many, the older classics are too heavy going, why not use the moderns whose outlook is more in tune with our own? Let the cinema be studied critically; despite the welter of nonsense, there is much that is excellent. The gramophone and the radio will give an introduction to music and musical appreciation, and there should be ample time for history and geography, both studied with an eye to modern affairs and the problems of citizenship. Lastly, there should be the conversational study of at least one foreign language, French, German or Spanish, to get the student to lose his self-consciousness and to talk. Physical training is also desirable at this stage.

At the end of the 'sabbatical' year, those students who intend to train for the more technical side of commerce or for one of the professions should proceed for their specialized training to an appropriate college, where they would be freed from the school atmosphere and where they could begin to make wider contacts than are possible in a school. Their preliminary training for an examination of intermediate grade should not extend over more than one academic year. That period is amply sufficient for any college student of ordinary ability and industry, and there are no advantages, and very marked disadvantages, in spreading that phase of the work over two years, as is commonly done in schools. By taking the preparation for the first university examination out of the schools, time would be provided in the schools for some final inculcation of general culture, and, if one may judge from the results of certain public examinations, the transfer of the intermediate work to other institutions would materially improve the chances of the students in passing their preliminary professional examination at the first attempt —a very desirable thing.

The idea here expressed is to provide a break between the generalized and the specialized periods of the education of a pupil, not merely to give an opportunity for the acquisition of some general culture, but to mark that there is at this stage a change in the character and conditions of the work. The non-specialized training in particular could and should be made to support some simple instruction on the more obvious connexions between science and ordinary life. Thus the adolescent, before he is plunged into the task of completing his professional training and before he is immersed in establishing his position, is given the opportunity of getting a general view of things which a year of freedom from training for an examination would offer.

The aim of education is not to get students through examinations. When a child has spent several of his most impressionable years in being trained to that end, it is not surprising that he finishes with an altogether wrong idea of the importance of examinations. A transitional period between school and college, with no examination in immediate prospect, might well awaken broader ideas and broader ideals, and so help on the development of that most desirable type of citizen, the man who has self-respect because he can think independently and can express himself clearly to others. Any ordinary man would be outraged if it were suggested to him that someone should eat his dinner, digest it, and then pass it on; few ordinary men are as yet outraged because their mental food is commonly treated in this fashion. This is but one of the many ideas which might become more common with the wider diffusion of generalized teaching in science, and with that wider diffusion and the closer study of the impact of science upon society there may also come the realization that the present organization of human society is largely unscientific. Society cannot become a better thing for the average common man until it is in accord with the scientific principles which that man can appreciate and approve.

A SENTIMENTAL JOURNEY

Black Lamb and Grey Falcon

The Record of a Journey through Yugoslavia in 1937. By Rebecca West. Vol. 1. Pp. xi+653+16 plates. Vol. 2. Pp. vii+586+16 plates. (London: Macmillan and Co., Ltd., 1941.) 42*s*. net.

In the eighteenth century, it was a diversion for those who could afford it to travel in a post-chaise through foreign parts, and thereafter to publish a gossiping guide, more or less observant and outspoken. Some of these works have become classics, and the practice is happily not extinct. But now one must go farther, one may travel faster, and by appointment one can see more various people; one also writes more gaudily than Laurence Sterne.

Here is a minutely annotated narrative of a spring tour in Yugoslavia in 1936. Rebecca West, already proficient in fiction, biography, and criticism, had lectured there the year before, and was fascinated by the land and the people. Though, as she says, she "knew quite a lot of Hapsburg history", she "knew nothing about the South Slavs"; so her industry has been great. But on her second visit she had a Government car with radio—a novel type of traffic-signal—a husband replete with common sense and restoratives, and as courier a Serbian official, Constantine, of Jewish descent, and resilient self-esteem, "one of the most gifted and learned men in Europe"; so the Serbian point of view was fully, though not exclusively, supplied. Of the Croat aspect of Yugoslavian affairs she is less well informed; her rare references to the Greeks are unsympathetic; she has no good word for Bulgarians, and she deliberately omits from her bibliography certain writers with whom she disagrees. But she liked the Albanians she met, and heard well of Albanians in general from her Serbian friends, and from Gospodin Mac, the wise manager of the Stan-Trg mine. As her own opinions incline to the Left, it was candid to describe as the most happy and prosperous community, where age-long feuds seemed to fade into mere neighbourliness, one created by foreign capitalists and governed by a Scottish dictator. Part of the trip was marred by Constantine's German wife, a repulsive character, cruelly drawn; and something went wrong, too, with Constantine; he was already ill at ease before he fades out of the book. Among all these aids and handicaps, two things are obvious: the ingenuous good nature of all classes of people, except a few political agents, and the personal achievement of Rebecca West and her husband, in eliciting so much intimate self-revelation and local commentary on what they were so fortunate as to see. Of the dialogues, some recall Thucydides' admission that his "speeches" were what might appropriately have been said.

Though the book, of some 1,200 pages, grows longer as one reads it, and has defects inherent in its circumstances and its technique, it has value for several reasons. First, it is a brilliant kaleidoscope of Balkan landscape, reviving treasured memories by its bold characterization of types, and insistence on the land's austere grip over man's fortunes, and on other men's devastation of laborious achievement. Some of this word-painting is difficult, like the pea- and plum-coloured landscapes that are skyed at the Academy; for colours, forms, and processes are oddly named—"savage" green, "sissy" flowers, "virile" water, "anfractuous" landscape, "enchanting camber" (the *profile* of an old bridge). Lake Scutari may be "earth's self-drawn ideogram, expressing its monstrosity" ooze-bound in greenish jelly (2, 426), but it is not a "fiord". Musical notation reinforces visual; internal disorder and sex-appeal lose vividness with iteration; mother-earth gives birth and is raped inordinately. The German girl condemned to an *Arbeit* on the works of West had scope for etymology as well as for æsthetic.

Then, of the people themselves, their racial types, and the thoroughbred humanity and physical grace of the best of them, there is direct and minute appreciation, and recurrent comparison—not new, but welcome confirmation from a fresh eye—with classical and Byzantine models, which are themselves only ideal because they embody just such personal experiences of contemporaries who could draw or write. Often we are on the hillside, not in Macedonia or Montenegro, but in old Ithaca, or with Achilles in his wrath.

Among these graphic glimpses of things seen and heard in such surroundings, the story, as Herodotus says, "loves parenthesis", groping back into medieval and earlier obscurity to answer Peterkin's question, "What they fought each other for"; and the answers lose nothing by being given before the tomb, or the church, or on the battlefield, which is landmark and datemark in one. Sensitive appreciation of Byzantine architecture and fresco-painting, and deeper sympathy than some historians have shown with Byzantine worship, enhance the perspective of secular events; many of which indeed ceased to be secular while the enemy was Islam, as they ceased again (so soon after!) when Cross met Swastika.

This leads to another and larger aspect of the book. In the spring, and especially at Easter, Orthodox belief finds expression in ritual, none the less potent, in the hands of a Bishop Nicolai, because much of it is not Christian at all. Here the "Black Lamb" of the title, a victim of St. George's Eve (2, 198*ff.*) provokes hysterical commentary, while Moslem incubation is condoned; and the "Grey Falcon" which brought King Lazar the choice between a temporal kingdom and an eternal (2, 292*ff.*) reveals him as "a member of the Peace Pledge Union" in distinguished modern company, and leads to a pendant onslaught on their political philosophy, preparing the way for an 'epilogue' to the whole book (2, 464*ff.*). These, like the fantasia on a foul latrine, and other incidents, are parenthetic writing at its weakest. But there is an adequate index.

There emerges—what has been hinted throughout the narrative—the writer's essential motive. After one of the Balkan conferences in 1913, one of the conspirators, congratulated on apparent settlement of claims, is said to have replied, "Well, there is always Serbia". It was the murder of King Alexander that roused Rebecca West to a sense of peril for herself and for all that she valued in this world. It was to analyse her own fears, and the motive for such crimes, that she devoted her gifts of eye and heart and pen; and she has brought her story on to the tragedy of April 1941, when the "Grey Falcon" came again. Much that she has written may be disputed now, some things may be refuted with fuller knowledge than hers. But she has seen much, studied widely, and thought hard, and it is not possible to read her indictment of the evils which have made South Slav fortunes so tragical, without realizing that what has happened in Yugoslavia does not differ in kind from perils that beset us all.

J. L. Myres.

AIDS TO AIR NAVIGATION

Astrographics, or First Steps in Navigation by the Stars

A Primer for the Airman Cadet. By Prof. Frank Debenham. Pp. v+118. (Cambridge: W. Heffer and Sons, Ltd., 1942.) 7*s.* 6*d.* net.

The Observer's Planisphere of Air Navigation Stars

By Ft.-Lieut. Francis Chichester. (London: George Allen and Unwin, Ltd., 1942.) 2*s.* 6*d.* net.

THE most reliable method of air navigation is by means of the celestial bodies. The time that can be devoted to training the air cadet in astro-navigation is necessarily limited. The air navigator can acquire all that he needs to know without much knowledge of mathematics, and can work more or less by rule of thumb; but the results are bound to be more satisfactory and the risks of error lessened, especially in an emergency, if he fully understands what he is doing. Prof. Debenham's little book has the commendable purpose of providing an easy approach to the principles involved by the use of graphic methods. A stereographic projection chart, with a matt celluloid rotatable disk, is provided to enable the spherical triangle to be solved approximately; stereographic scales are also provided, which make a somewhat greater accuracy attainable. These graphical methods undoubtedly give a greater insight into what is being done than is possible by the routine use of mathematical formulæ, and the cadet who studies Prof. Debenham's volume with understanding cannot fail to benefit from it.

A well-chosen series of exercises is added, to which solutions are given.

The book is unfortunately marred by a number of statements that lack precision or that are badly expressed, such, for example, as the following: a magnetic bearing is measured from a magnetic pole, which attracts compass needles, but does not stay in one place; the equator encircles the largest part of the earth; the parallels of latitude are equidistant from each other; on June 21 the sun's path is overhead all day along the Tropic of Cancer. It is stated that sidereal time is "a very useful kind of time, easily checked by observing any star's passage over the meridian, and with no tricky corrections to be applied"; this is not correct, for there are true sidereal and uniform sidereal times, just as there are apparent and mean solar times. The essential features of the Air Almanac are not explained; it is stated that "the airman wanted something handy in size, easy to understand and not burdened with too great a precision", yet the Air Almanacs for a whole year necessarily occupy a greater compass than the Abridged Nautical Almanac for seamen.

The use of haversine formulæ and tables could well have been omitted and a brief description given of tables providing a direct solution of the spherical triangle when an assumed position has been adopted; such tables are much more convenient and suitable for use in the air than logarithmic haversine tables.

Every air navigator should be able to identify with certainty the stars that are used in the Air Almanac, not only on dark clear nights but also on moonlight nights and with broken cloud. The special air navigation stars have been selected from among the brightest stars so as to give a reasonably good distribution over the sky. In the planisphere prepared by Flight-Lieutenant Chichester, these stars are shown, with sufficient additional bright stars to aid in their identification. The twenty-four principal stars, the altitudes and azimuths of which are tabulated for different hour-angles and declinations in the Air Navigation Tables, are indicated by name, the remaining navigation stars by their numbers in the Air Almanac, while the other stars shown are numbered and their names given in a key. The planisphere shows the air navigation stars visible at any time of the night or year to observers in latitudes 50° N. and 35° S. It should be a great help to air cadets in learning to identify the stars required for navigation.

H. Spencer Jones.

UTILIZATION OF STATISTICS IN RESEARCH

Statistical Methods for Research Workers

By Prof. R. A. Fisher. (Biological Monographs and Manuals.) Eighth edition, revised and enlarged. Pp. xv+344. (Edinburgh and London: Oliver and Boyd, 1941.) 16*s*. net.

Since its first appearance in 1925 Prof. Fisher's book has become the standard manual of statistical practice for research workers throughout the English-speaking world, and new editions continue to be called for. This eighth edition follows the same lines as its predecessors, which have themselves grown from the first mainly by the insertion of supplementary material throughout the book, not by structural alteration.

One of the signs of the success which the book has enjoyed is a change in methods and emphasis over the last seventeen years which would have justified a rather more drastic revision. The author evidently feels this himself, for in the preface he excuses himself from "The difficult task of a fundamental re-arrangement" on the grounds that "it is of real value to understand the problems discussed by earlier writers and to be able to translate them into the system of ideas in which they may be more simply or more comprehensively resolved". Perhaps so, but we may hope that on some future occasion Prof. Fisher will be able to find the time and opportunity to remould the book a little nearer to the heart's desire.

In some respects this is a difficult book, partly because of Fisher's condensed style and partly for a more important reason. The theory of estimation and the exact tests of significance with which it deals are based on ideas and derived by mathematics which are quite outside the ambit of the average research worker in the so-called natural sciences. It would have been impossible to give anything like a complete account of the theory in a monograph restricted to method; and thus the author was practically compelled to the course which he finally adopted, and to describe only the technique of his methods and to exemplify their use. In consequence the reader has to accept important results without proof and often without any hint as to how they were derived or precisely what hypotheses underlie them. If he is sufficiently interested and has the leisure to look elsewhere for the basis of the authority so much the better; but he will not find it in this book, and it is difficult to see how Fisher could have provided it without expanding a relatively short handbook into a comprehensive treatise.

This raises the question how far the powerful methods of modern statistics can be properly applied without some conception, however general, of their rationale. Its importance is heightened by the fact that the book, though not intended as a course of instruction for statisticians, is often referred to as if it were. Fisher has, in fact, suffered from a want of self-control on the part of some of his disciples, who betray a rapturous and undiscriminating enthusiasm which would be out of place even at a promenade concert. This in turn has excited a certain amount of criticism of the book. Orthodox statistical teachers have expressed doubts whether Fisher's broomstick can safely be entrusted to any apprentice who can memorize an invocatory formula. It is replied that one can use a telescope intelligently without being an optician. It is retorted that only qualified practitioners are allowed to administer powerful drugs. This sort of argument trails indecisively through a good deal of the statistical literature of the past fifteen years, but the whole question is one which might well be seriously discussed. In a large laboratory the difficulty may be overcome by the employment of a statistical specialist, and perhaps as research becomes more centralized the problem of the individual research worker who has to be his own statistician will disappear. But the question how far a knowledge of statistical *theory* is an essential part of the equipment of a research worker remains unanswered; it is a problem which could with advantage be studied by those responsible for the training of such workers.

However that may be, the influence of "Statistical Methods" on scientific method has been profound. To Fisher and his school goes the credit for having brought home to scientific workers two things. One is that the proper use of experimental data is itself a science which can be brought to a high degree of precision, even when the material is imperfect and the sample small. The second is that though in certain sciences and in certain classes of experiment error cannot be reduced, it can be controlled by experimental design. This latter lesson, indeed, has been inculcated by Fisher in a separate book and has not yet been fully learnt by research workers. It is a useful rule that statistical advice should be sought *before the experiment is carried out.* Most statisticians have met the case in which the results of an experiment could have been given a much greater significance, very often without additional trouble or expense, by adequate design at the outset of the inquiry.

Notwithstanding the interest aroused by the newer methods in statistics as applied to experiment, "Statistical Methods" has few competitors. To some extent this is due to the fact that it is largely a record of Fisher's own achievements, but that is not the whole story. The challenge of Fisher's ideas and his long record of success have made this book a sort of symbol of a new statistical creed and a banner around which his followers rally themselves. Research workers will long continue to buy this book, to wrestle with its ideas and to apply its methods to an ever-enlarging field of discovery.

M. G. Kendall.

PHYSICAL BASIS OF RADIOLOGY

Radiology Physics

An Introductory Course for Medical or Premedical Students and for all Radiologists. By Prof. John Kellock Robertson. (Textbooks on Physics.) Pp. xv+270. (London: Chapman and Hall, Ltd., 1941.) 18*s*. net.

THE applications of physics to medicine increase rapidly in number and scope, and there is great need of books which attempt to set forth the fundamental principles underlying these applications, either from the point of view of a fairly elementary student or from that of a more advanced worker in the subject. Prof. J. K. Robertson's book is addressed to the first of these possible audiences, and is a most welcome addition to the literature.

It is described as "an introductory course for medical or premedical students and for all radiologists" and represents a course of physics which is given to medical students at Queen's University (Kingston, Ontario) after their first-year preliminary training in physics. It is perhaps worth noting that the American Association of Physics Teachers is in favour of making the physics pre-requisite two years instead of one; this is a question which may well exercise those in Great Britain who are responsible for the scientific training of the medical undergraduate.

The book contains chapters on alternating currents, the production of high voltage, the "measurement and control of high tension voltage", cathode rays, positive rays and isotopes, Röntgen-ray tubes, valve rectification, general properties of X-rays, electromagnetic waves, measurement of wave-length of X-rays, secondary X-rays and absorption, Röntgen ray dosage, radioactivity, supervoltage tubes and high-speed particles, artificial radioactivity and high frequency currents.

The book is well written, though we may perhaps be allowed to protest against the title "Radiology Physics" or such phrases as "control of high-tension voltage" which sometimes occur, but such verbal infelicities are rare. Occasionally it seems that the order of certain sections might be altered with advantage, as for example the high-frequency current section, which might be brought forward into the earlier portion of the book dealing with electrotechnical matters, while the discussion of X-ray quality measurement and half-value layer would perhaps be more intelligible to the student if it followed the discussion of absorption and absorption coefficients.

In further editions of the book—and there should surely be others—the discussion on electromagnetic waves might also be expanded and more detail included. Possibly the difficulty arises from the fact that the book is intended for use by those who are presumed to have had the first-year instruction, but standing alone it seems advisable to discuss the elements of infra-red and ultra-violet physics more fully and more fundamentally than is actually attempted. The section concerning the relation of focal spot to wave-length is also isolated and might advantageously be expanded.

The diagrams are generally very clear, simple and accurate, but in spite of the legend the bending of the positively and negatively charged rays towards the poles of the magnet (Fig. 141) is rather misleading. These details are, however, very small blemishes on an excellent book which covers a large amount of ground simply, clearly and accurately, and the author has rendered a considerable service to physics in medicine by writing it. There can be no doubt that it will be very generally used in the training of both undergraduates and medical radiologists.

W. V. Mayneord.

RUBBER AT A TURNING POINT?

Rubber and its Use

By Harry L. Fisher. Pp. xvi+128. (London: Macmillan and Co., Ltd., 1941.) 7*s*. 6*d*. net.

DR. FISHER's small work is a model of excellent compression. Avoiding side issues and technical minutiæ, the book gives a clear, accurate and balanced picture of the development and present state of rubber science and technology. All the usual topics of a popular descriptive work of this kind on rubber are present. There are chapters on early history, sources of crude rubber, the plantation industry, crude rubber itself—its nature, properties, compounding and manipulation in the various manufacturing processes. Novelties arising out of the relatively less familiar processes of latex manufacture are not omitted. There is a revealing outline of the main types of vulcanized rubber articles, and a few pages on synthetic rubbers and on the chemical derivatives of crude rubber bring the discussion into the most recent trends of development of the industry. Dr. Fisher has had seventeen years experience with the large American rubber companies and, as he states, extensive experience in lecturing to student groups; from these experiences he has compounded the correct ingredients for a popular work remarkably well. Good illustrations add interest for the lay reader.

The present crisis in rubber supplies, created by the over-running of the Far Eastern plantations by Japan, has brought rubber forcibly to every mind and makes the present book timely even if the crisis itself is no part of the text. The crisis indeed may well make this book the last summary of one particular epoch in the story of rubber. There is no question that the only way out of the impending rubber scarcity is by way of synthetic rubbers. Reclaimed rubber and vulcanized oil substitutes are emergency palliatives of the first importance, but the rubber industry cannot live indefinitely on reclaim and factice. We are thus destined in the coming decade, and perhaps for much longer, to extensive use of synthetic rubbers of several types aggregating possibly half a million tons a year when production reaches that figure in the next three or four years. Such a transformation of the rubber industry undoubtedly marks a turning point in its history of incalculable significance.

Both manufacturers and users of rubber articles will find fundamental differences between the coming epoch and that which is now closing. Whether we shall be able, or will wish, to return to presen practices in the future is a complicated technical and economic problem of which no one can foresee the ultimate outcome. Dr. Fisher's book may well live as an apt summary of an epoch not destined to return.

Nutrition and the War

By Dr. Geoffrey Bourne. Second edition, revised and enlarged. Pp. xii+148. (Cambridge: At the University Press, 1942.) 4*s*. 6*d*. net.

IN these days of fortress economics, a special responsibility should burden those who set out to give information about food to the multitude, and it is only fair that their books should be submitted to searching criticism. From such a stern test Dr. Bourne's book emerges certainly not unscathed but with its fabric still fundamentally sound and a prognosis of useful service. It is entertainingly and well written and in places surprisingly up to date; its successive chapters deal in simple language with energy and food; proteins, fats and carbohydrates; vitamins; minerals, and nutrition in war-time. Nearly half the book is taken up by tables setting out the calorie, protein, carbohydrate, fat, mineral and vitamin content of a variety of products.

The advice given in the book is on the whole sound. At times, however, it is detached from reality, as in the author's unnecessary insistence on the paramount importance of citrus fruits, which are almost unobtainable, and his failure to indicate the excellent though more homely sources which everyone can produce in garden or allotment. A more serious point is the lack of appreciation that it is not so much the richness of a product in any given food factor as the amount consumed that matters in the end. This leads to the strange selection of curry powder as the best source of iron, and of 'Marmite' as nearly the best source of calcium. Alcohol gets an unexpected pat on the back and one almost fears that this misinterpretation of Mitchell's work might lead an enthusiastic planner of the family diet to prescribe it to children to make them grow faster and put on flesh. Fortunately, the commodity is in short supply. The weakest part of the book are the tables, which contain many mistakes. (Watercress and tomatoes are given as poor in vitamin A, but oranges and wholemeal flour are classed as fairly good; dried peas, beans and lentils are recommended as a source of vegetable fat, and so on.)

Frankly, Dr. Bourne will have to study his Fixsen and Roscoe and his McCance and Widdowson and do some drastic revising. The book is worth it and one looks forward to an improved third edition. Let us hope that by then a change in the title will also be needed.

S. K. KON.

Tables of Physical and Chemical Constants

And some Mathematical Functions. By Dr. G. W. C. Kaye and Prof. T. H. Laby. Ninth edition. Pp. vii+81. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1941.) 18*s*. net.

N the last thirty years this valuable set of tables has become so indispensable in the physics laboratory that every laboratory boy knows what to get when asked for "Kaye and Laby". If authors' names alone were to be used, accuracy would demand that far more than two be mentioned, for the original authors adopted the wise policy of securing the help of many others. As this edition, the ninth, was passing through the press, Dr. Kaye died and the Physics Department of the National Physical aboratory gave a final inspection to the text and prepared the index. Prof. Laby, who took no part in the preparation of the eighth edition, has re-ritten for the present edition the tables dealing ith units and dimensions, electrical units, conversion factors, mechanical equivalent of heat, velocity of light, general and atomic constants, α-rays, radioactivity, isotopes and arrangement of electrons in atoms. In one section the tables are ahead of time, because they include the electrical units originally proposed for adoption as "absolute" from January 1, 1940, by the International Electrotechnical Commission. The War upset the plan for general adoption.

The publishers have managed to find good paper for this edition. Twenty pages have been added to the book, and four shillings to the price.

W. H. G.

Mathematics for Technical Students

By A. Geary, H. V. Lowry and Dr. H. A. Hayden. Part 3. Pp. viii+393. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1941.) 8*s*.

THIS is the third part of a series designed to provide the basic mathematical equipment for technical students, and to meet the requirements of the national certificate courses in engineering, building and chemistry. Each volume is planned to cover a year's work; the book under notice is thus intended to provide the necessary subject-matter for third-year students.

After a useful chapter on revision, the text begins with the progressions, binomial series, graphs of exponential functions, and the trigonometric addition theorems. The ground is accordingly well prepared for the calculus which follows. The modern method of developing the principles of differentiation and integration, side by side, is well carried out, and illustrated by applications to mechanical and electrical engineering. The final chapters are devoted to complex numbers, with applications to alternating currents, and alignment charts. There is a valuable summary of formulæ followed by a number of specimen examination papers. The student is well provided, at the ends of each chapter, with exercises for practice, to which answers are supplied. The book also includes an index and the usual set of tables.

Intermediate Algebra

By Neil McArthur and Alexander Keith. Pp. x+356. (London: Methuen and Co., Ltd., 1942.) 8*s*. 6*d*.

THIS excellent book reveals the rapid strides which algebra has made in recent times. A few years ago, "Higher Algebra" would most probably have been the appropriate title. The course is designed primarily for use in school and first-year university classes, the students of which have previously covered the work required for the first school certificate examination. The text deals, in a comprehensive way, with polynomials, partial fractions, equations, including determinants, indices, logarithms, simple series, graphs and the binomial theorem. The authors have provided a stimulating introduction on the basis of the course which should give the student an intelligent interest in the subject. Mention should also be made of the important chapters on graphs and the method of differences which lead, quite logically, to the calculus. Modern methods have been used throughout, and the treatment, in general, is not only sound but also very clear and well illustrated by worked examples. The aim of the authors has, indeed, been skilfully carried out and, as would be expected in such a book, ample exercises for practice have been supplied. Answers to these are given and a good inde [illegible] ided.

ENGLISH IN THE SCIENCE COURSE*

By HUGH LYON

Headmaster of Rugby School

THE Spens Report distinguishes three main purposes of English teaching: the first, "to enable a child to express clearly, in speech or writing, his own thoughts and to understand the clearly expressed thoughts of others"; the second, "the development of the power thus acquired to benefit the child as a social being, and to help him take his place as a thinking individual and a wise citizen"; and the third, "the training in the appreciation of literature". This division provides a useful basis for discussion, though it must of course be recognized that we are often, consciously or unconsciously, aiming at more than one of these objectives simultaneously. Indeed, the consideration with a class of any vital piece of literature should call into play both clear expression and comprehension, understanding of the subject-matter and literary appreciation.

I should like at the outset to deal with the vexatious matter of overcrowded time-tables. Science is a perpetually growing and expanding study; and though this may be, educationally, a stimulating and valuable thing, it is becoming a real difficulty to the administrators. Much of the work which was once done at universities is now delegated to the secondary school. The situation is becoming serious on the medical side, and real attempts are at last being made to meet it. But unless science teachers can discard old knowledge as rapidly as new truths are discovered there seems to be no real solution to the problem. It is easy enough in most other subjects; once we have grasped the geographical truth that the earth is round, we have not added to our curriculum, since there is no serious reason why we should continue to devote lessons to explaining that it is flat. And language study and even history can select for educational purposes from a field which, however far it extends, will never be too large for them. But science demands a knowledge of the whole, since (unless I am misinformed) it does not admit of short-cuts or arbitrary selection; it is moreover a practical study, which involves long periods in laboratories and considerable sacrifice of spare time. So it is not surprising that the young scientific worker is always in danger of over-specialization.

To my mind the minimum of non-scientific work a science specialist should do in a thirty- to thirty-four-period week is between ten and twelve periods: two of scripture, two of physical education, three or four of English, and three or four of a modern language. He should also have enough spare time to follow some non-scientific hobby, music or art or something of that nature. I have called this a minimum, but it is, I fear, a minimum very seldom attained and scarcely ever exceeded.

Up to the school certificate there is a blessed compulsion laid upon us all to keep the curriculum broad, and English normally gets its fair share of attention. But where other subjects are handicapped merely by the unfamiliarity of their context (whether this be Greek characters, French verbs, algebraical symbols or chemical formulæ) English has to struggle against the much more dangerous fact that most of those who are taught it think they know all about it already. Ideally, the first object of English teaching, training in simple expression and comprehension, should have been attained before the children reach the specialist stage. But this is not so, and often the young students who start on their special science course with a first certificate of general educational proficiency tucked into their pocket are in most cases incapable of expressing themselves clearly, either orally or on paper, and liable to make complete nonsense of a closely reasoned paragraph of simple prose.

One of the smart things to say about this business of teaching expression is that every master is an English master, and that teachers of other subjects ought never to pass slovenly or badly written answers. This is admirable doctrine; but there are two difficulties. The first is that it assumes that this part of English teaching can be done by a non-specialist (yet would the science teacher trust the English teacher to teach anyone even the rudest elements of science?). The second is that when the science teacher asks questions he is concerned to get answers which are right in substance; credit is given—and rightly—for accuracy in matter of fact, and the quality of expression must be a secondary consideration. Moreover, whereas in language teaching English style comes to its own in all translation work, mathematics and science deal largely with symbols and not with words. The science master's main opportunity comes in requiring descriptions of experiments; this is admirably designed to test clear and accurate statement, since slipshod explanation defeats itself. Yet beyond correcting obvious errors and pointing out how defective expression distorts or obscures the truth, the science teacher as such can do little; he has not the time and it is not his job. Yet if he will just do this he is assisting the English teacher more than h realizes; for he has helped to break through th water-tight compartments between one school 'sub ject' and another, and taught his pupil (who alway pays more attention to his specialist teacher than t any other) that good English is a means to somethin beyond itself.

The main fact remains, however, that the English master can neither assume that his pupils have bee taught to express themselves and understand any thing beyond the simplest books in their earlier year nor delegate this part of his duty to the scienc department, though he will hope for its co-operatio He must do the work himself. How then will h do it?

Partly, I think, by direct and formal instructio in syntax, grammar, punctuation and style; the are several ingenious books available which mak these things palatable, and the teacher should quick to seize any opportunity of using an odd fiv minutes in some such exercise. Indirectly, too, i the correction of essays or answer papers, he will ha chances of directing attention to the pupil's besetti sins and suggesting remedies. These sins are of var ing degrees of seriousness, and in some cases betr secrets of deeper disorder. Bad spelling may be car lessness or lack of observation or an eradicable a sometimes inherited disease; but there is nothi inherently vicious in it. Mistakes of grammar a syntax indicate a misspent youth and a sloven habit of speech. A clumsy style suggests a lack æsthetic sensibility and a lumbering mind. But no of these are so depraved as the commoner failing bad punctuation, which is the sure reflection of i accurate and slipshod thought. Commas and sen colons are as much part of the expression of an idea as the words in which it is embodied. They are not (as often seems the case) condiments to be sprinkled freely over the completed paragraph.

---

* Substance of the presidential address at the annual meeting of the Science Mast [illegible] lation held at Rugby School during April 8–11.

Oral expression should not be forgotten, though there is all too little time for it.

Hand-in-hand with expression goes comprehension. Boys learn to read very many years before they learn to understand, and considerable practice is needed before they can be relied on to extract the meaning from any but the simplest passages. Many of them cannot follow a set of instructions or the steps of a straightforward argument, so it is not surprising that they show such helplessness when confronted by a fairly stiff passage of Shakespeare or one of the more elementary official publications. Much here depends on practice, which is all the more valuable since you cannot test comprehension without giving training in expression as well. All good first school examinations include a précis, but this useful exercise tends to drop out of the curriculum later. Yet there is nothing like it for testing three most important things: first, the ability to realize what the writer means; secondly, the power to distinguish between the essentials and non-essentials in the matter presented; and finally, the art of expressing the gist of it in clear, simple prose.

The second and more important stage of English instruction is "the development of this power [of comprehension and expression] to benefit the child as a social being, and to help him take his place as a thinking individual and a wise citizen". The distinction between this and the previous stage is one of emphasis rather than of method or subject-matter. From the beginning there must be some care taken in the choice of the material for the English lesson; comprehension and expression cannot proceed *in vacuo*. But as the boy gets older we should be free to consider more and more not only how he expresses his thought but what his thought is like and how it is developing and expanding; and at the same time we should be demanding of him a deeper comprehension and a critical examination of the thoughts of others.

There will of course be scope for his thought and his critical power in his specialist work, but now that psychologists have more or less agreed that there is considerably less transfer of training than was once supposed, we cannot assume that an understanding of grammatical or biological variations will show itself in a clear grasp of political or moral distinctions. It is notorious that many men of outstanding ability in their own field have gone sadly astray when they have moved out of it. The same failure to transfer ability from one subject to another is found in all spheres of knowledge, and we must therefore not imagine that when we have taught a boy to make accurate deductions or detect fallacies in his own subject he will be able to do so in all. Still less, of course, can we introduce him to the material of other branches of study by means of his own special subject. It is here that English, which is for us the connecting medium between all our diverse little worlds, comes into its own.

We have already demanded ability to express and to understand simple ideas; we might go on to say that an educated man should have achieved some general philosophy of life and have accumulated some information about the world in which he lives. He should know roughly how it is arranged spatially and the broad outlines of the experiences it has gone through in the past two thousand years. He should be able to think politically, and have some convictions on questions of ethics and community life. Most of us would of course go much further than this, but here at any rate is a minimum for our consideration. How far in our English course are we helping boys to achieve the end desired?

The first necessity is to arouse their interest, which can be amazingly hard to do. The more absorbing a subject, the more it tends to fill the horizon; and the more frequent and searching the examinations, the less time there is for the cramped student to stretch his arms and grow to his full stature. "Born a man and died a grocer"; that is the epitaph of all those whose one aim in life is to go on knowing more and more about less and less. My experience as one of the board of interviewers for county major scholarships has revealed some rather dark corners of the educational field. Some of the candidates who have come before us, not infrequently those who are the most brilliant in their own subject, have never lifted up their heads to sniff the breeze and see the stars. They prate happily to us of the laborious progress they are making towards their next examination, confess at times to a mild fondness for the pictures or a penchant for draughts; at times they bicycle for exercise and are occasionally known to dig up weeds. But their world is sealed and they are comfortably at ease within it. The War has now, in its third year, battered a little rudely at their peace, but that after all is an interruption which in time will pass. But as for politics in the deeper sense, philosophy, mountain-climbing, music, literature, long walks in moonlight, bathes in sunlit streams, social problems, art, the blessed frenzy of argument, passion, adventure, God Himself—try them where you will and the bland, blank smile of polite boredom is your only answer.

This is of course a caricature, but like all caricatures it suggests a truth; and with all deference I must go on to say that almost all those candidates to whom it applied were specialists in science. It is not that science is in itself a narrowing study; but it demands so much time, and the standard required for success in examinations is so high, that literary, political, ethical, historical, philosophical and cultural interests all have to give way.

If we are to interest boys and girls in subjects to one side of their main line of advance, we must show them how necessary it is for them to explore the roads which lead to them. We must ask questions of them, questions which seem to them (as well as to us) to be important, questions to which they are anxious to know the answers. The mere unloading of information is of itself unappetizing, unless it either is immediately relevant to their particular subject, or comes in response to a demand. It follows that we should probe them a little, try to find by judicious inquiry where their imaginations are not dead but merely sleeping. If they have learnt at all to read (and courses of silent reading lower in the school should help towards this) we can discover which way their minds have been moving by letting them write an essay on any subject (other than science) under the sun. This for a start; it may give us a line of approach. Class debates and informal discussions will test them further; once their interest is on the move it should be kept spinning by any and every means, by provocation, by challenge, by illustration, by trenchant criticism, by genuine sympathy. But if the teacher, from his eminence, thinks fit to be superior or sarcastic or condescending—then small wonder if our young scientist returns gladly to his laboratory, thinking with savage glee as he completes his analysis how hopelessly lost his English master would be inside those sacred walls.

All this does scant justice to those few young scientific boys who have been among my own keenest and best-informed English pupils in the past few years. But it must be confessed they were the exception, and that both in quantity and quality the essays on political or general subjects shown up to me by my Science VIth have compared badly with those from the Classical or Modern sides. There are three stages through which young writers normally pass: that in which their essays are too short, because they have little to say; that in which they are too long because they cannot control their material; and that (reached only by the few) in which they have suited their length to their subject, having learnt to select and arrange both their thoughts and their words. Too often I find that, while I have to wade through vast compositions by young historians and modern linguists who have reached the stage of verbosity and cannot emerge from it, the comparative brevity of their scientific brethren is due more often to their having failed to pass out of stage one than to their having graduated into stage three.

Training in the appreciation of literature is a chancy business; it depends more than almost any other co-operative activity upon the nature of the two parties to the operation and upon the *rapport* between them. But if the pupil is to make our great heritage of literature his own he must both be sensitive himself and sit—at some stage in his career—at the feet of one of the chosen votaries of Apollo. All too often he enters upon his specialist course in none too congenial a mood. He may well have suffered under the meticulous dissection of a play of Shakespeare and the minor poems of Milton by a teacher whose horizon was bounded by contexts and classical allusions and the percentage required for a credit. In this teaching the teacher must be sincere, both in judgment and in enthusiasm. The teacher must also be sincere in criticism, such as frank recognition of Shakespeare's ludicrous failures as well as his triumphs. Such teachers win respect, and respect for them is half-way to interest in their enthusiasms. The second suggestion I would make is that here as in the earlier stage much can be done by asking questions which excite a desire to know the answer.

It is not for everyone to find in literature their chief delight. But we shall do our pupils wrong if we do not endeavour to reveal to them all what abiding happiness can be found in the company of great writers. This is after all the crowning achievement of the English teacher. To ensure moderately clear expression is much, and the first step to creating an intelligent electorate. To awaken interest in social, political and moral questions, this is more, and an enrichment of the life of man. But to open the doors of the imagination, this is best of all. For we are all of us, scientist and humanist alike, citizens of two worlds; and nothing that happens in this unhappy, tortured planet where man is at enmity with man can altogether overwhelm one who has heard the lute of Orpheus, or thrilled to the passion of Romeo, or looked with startled eyes through Keats's casements upon the foam of perilous seas.

THE SCIENCE MASTERS' ASSOCIATION

ANNUAL MEETING AT RUGBY

THE first full annual meeting the Science Masters' Association has been able to arrange since the outbreak of war was held at Rugby School during April 8–10, under the presidency of Mr. Hugh Lyon, headmaster of the School. The success of the meeting justified the venture; more than two hundred members were resident in school Houses, and many others made daily visits. The lectures were stimulating, discussions fruitful even when they developed unexpected trends, visits of particular interest, and the members' exhibition as good as any of its predecessors.

A liberal education draws its energy from many sources. It is a narrow kind of humane education which neglects the study of natural science; but it is a sterile form of scientific training which takes little regard of human relationships. The presidential address on "English in the Science Course" (see p. 454) and the biennial Science and Citizenship Lecture on "Biological Instruction and Training for Citizenship" given by Prof. Lancelot Hogben left the mind open to the wider views of life.

Biology and Citizenship

Prof. Hogben aimed high. He endeavoured to approach the great national and political problems caused by the impact of science on society. At the start of his lecture he cleared the air for what followed by examining the ideal of knowledge for its own sake.

Knowledge for its own sake presumably means knowledge for the sake of the individual, the pursuit of knowledge for the satisfaction of personal curiosity; and it goes without saying that individual curiosity is a necessary condition for the growth of knowledge. To that extent knowledge for its own sake is a formula which directs attention to a legitimate aspiration and to a sound educational principle. Most of us, including those alert to social agencies which provide scope for personal curiosity, would readily concede that personal interest in a particular line of inquiry or instruction depends on circumstances which do not necessarily or commonly have a close connexion with its social usefulness. Few of us imagine that precocious concern for the remediable evils of malnutrition determines the choice of a career in biochemistry. What we do assert is that a society more alert to the problems of malnutrition would furnish more ample opportunities for biochemical research and instruction. We find it difficult to understand why biochemistry should suffer from the efforts of those who wish to promote greater public esteem for the work which biochemists carry out; and we are not convinced that a person who professes supercilious indifference towards the welfare of his fellow-citizens is on that account a better biochemist.

If they mean anything at all, this seems to be what people suggest when they make knowledge for its own sake a battle cry in the discussion of science teaching in relation to citizenship. There is nothing particularly scientific about the egocentric attitude which refuses to recognize social relations as data relevant to personal conduct. That we are members of a social group is an inescapable fact. To what extent we get opportunities and encouragement to pursue our own interests depends on whether the pursuit of our interests harmonizes with the interests of others. In a democratic society this depends partly on whether we can convince our fellow-citizens that the pursuit of our own interests will benefit them. To conceal these simple considerations behind fine phrases such as 'knowledge for its own sake' merely shows lack of imagination and common sense. If personal curiosity is the only justification for the study of biology, there are no sufficient reasons for promoting its study as a school subject. Biology can justify its claim to a place in universal instruction if, and only if, it can establish its credentials as a branch of humane scholarship, that is to say, as an essential part of the intellectual equipment of the individual for the responsibilities of citizenship. This presupposes a common basis of agreement concerning civic obligations and privileges.

As a definition sufficient for the purpose of constructive discussion Prof. Hogben suggested the following. Those of us who subscribe to the democratic process believe in promoting social adjustment by rational assent of those concerned. Specialists need educating to a rational appreciation of the social value of professional work they perform. During the past twenty years the Fascist and Nazi regimes have systematically reorganized education to promote and consolidate totalitarian values and institutions. During the same period can any single country claim to have an educational system designed with equal singleness of purpose to encourage the survival of democracy ? The pioneers of British democracy did have definite views about the type of education which democratic government calls for ; but the curriculum of our educational institutions has not kept in step with the changing functions of democratic government. What views about education for government are widely prevalent in influential circles are a 'hang-over' from a period when the functions of democratic government were very different from what they are to-day.

To a large extent the change is due to the impact of scientific discovery on human society. If the functions of democratic government were still as when Milton claimed the right to know, to utter and to argue freely according to conscience, they would be equally important assets to-day. They are not. Our outlook is necessarily different from that of Milton's contemporaries. Meanwhile, we have patched up an educational system which served the needs of democracy well enough in the eighteenth century by making provision for the training of specialists for industry. There has been no radical change of the practice of education for government. What units of government are most suitable to changing conditions, and what new tasks Government can undertake in the interests of citizens increasingly become technical issues for which historical erudition supplies no precedent. Intelligent social decision depends on understanding what technical possibilities are realizable.

The fact that scientific knowledge can discipline human beings to cease striving for what they cannot have is not the only way in which it affects social values. Diffusion of scientific knowledge has a more positive role. To say that public health is now one of the major preoccupations of Government is to say that scientific discovery, and diffusion of knowledge by its implications, have enlarged the scope of human co-operation by enlisting us in a common struggle. Out of this new awareness of common dangers is coming to birth a new social phenomenon, the rational recognition of common needs which transcend our conflicting wants. We are learning to discuss whether people have the vitamins they need and to ensure that they get them. To the extent that we do so, the virus of scientific rationality is infecting politics.

The demand for biological teaching in the school is a new thing, and there is a widespread sentiment in favour of providing biological instruction of a sort suitable to the needs of pupils not destined to become professional biologists. There is much to be said for the provision of a more flexible curriculum in the universities and for the introduction of a general science degree for teachers ; but the administrative difficulties are great, while too many professors approach the issue with more concern for departmental prestige than for the civic value of what they can contribute. Biological instruction which can justify its claim to a place in a curriculum designed to promote intelligent citizenship must give prominence to aspects of biology which are most relevant to human needs. A comprehensive treatment of the field would emphasize the following themes :

(*a*) Animal parasitology, mycology and insect pests, that is, pests and parasites of man and of domestic animals or cultivated plants.

(*b*) Genetics in relation to plant and animal breeding.

(*c*) Bacteriology, serology and chemotherapeutics.

(*d*) Soil conditions and plant nutrition.

(*e*) Animal nutrition in relation to animal husbandry ; human nutrition, respiration and excretion *vis-à-vis* occupational diseases, and animal husbandry.

(*f*) Physiology of reproduction.

(*g*) Interpretation of vital statistics.

Prof. Hogben then dealt in detail with the broad background required, and the framework of specialized studies to be erected on it.

Biology as a Social Science

The lecture by Prof. Lancelot Hogben lent strong support to the main points raised by Mr. L. J. F. Brimble during the previous afternoon, when in a lecture entitled "Biology as a Social Science" he not only pleaded for a more definite realization in schools of the sociological implications of biology but also dealt with the practical ways in which teachers could put these to effect. At this lecture Mr. H. P. Ramage (Gresham's School) was in the chair.

There is a widespread feeling that the study of man should have a larger share in all general biology courses. This has, however, been wrongly interpreted by some. For example, certain biologists, especially in the universities, have expressed the fear that this might lead to man being used as a biological 'type'. Mr. Brimble dissociated himself from this view. In any event he gave reasons which he amplified later for considering man as an undesirable type in biological teaching because in certain fundamentals he is the exception rather than the rule. Another reason for emphasizing the sociological impact of biology is the strong movement which is now taking place in favour of the development of the social sciences, both in research and in education.

Mr. Brimble expressed his concern over the tendency of many teachers to make their science teaching too heuristic, in that they lean too much towards teaching science in the spirit of research and discovery. This may be all right in the universities but in the schools it leads to the students missing other aspects of their studies which are of equal importance. There is considerable danger involved in pressing for more practical work in schools. It is true that practical work well taught is of inestimable value, but it runs the risk of becoming biased in favour of the potential scientists. Practical work cannot, of course, be abandoned altogether since it is essential in order to drive home basic scientific facts and to satisfy the fundamental instincts of the pupil. To inculcate in the average schoolchild the spirit of discovery is, of course, very desirable, but by far the majority have no intention of taking up science as a profession in later life and many of them in any event have no leaning that way, yet those young students can derive as much benefit from a properly organized course of school science as any student who proposes entering the university as a science student. It is difficult to say what cultural benefit any boy or girl can derive in later life from an empirical knowledge of the analytical tables or of the structural formula for soap. On the other hand a knowledge of the everyday applications of chemical analysis can have certain cultural repercussions.

In biology as in any other science one must realize that though there is a minority who intend following careers which demand some detailed knowledge of biological science or medicine, and although these must receive consideration for the sake of the advancement of science, on the other hand much more consideration must be given to the fuller education of all students including the potential science specialists, in which historical background, the philosophy of science and the impact of science upon society have a full share of consideration.

One important factor, however, must be taken into consideration in all stages of the student's school life, and that is the time factor. Teaching hours are comparatively short—about thirty hours a week. If the ideal educational syllabus is to be achieved, however, one must decide what shall be taught and how much of what, and in coming to this decision the dead wood must be cut out and new shoots encouraged. This applies not only to the subjects themselves but also to the content of each individual subject, as emphasized also by Mr. Lyon. In other words, a more balanced curriculum is desirable and this must be periodically revised. In spite of the time factor, if it can be agreed that any subject, no matter what it is, shall be taught in schools, then time should be found for it, and in Mr. Brimble's opinion biology, which after all is the science of life, should be taught in all schools.

Mr. Brimble also discussed the dominating and destructive effect of the examination syllabuses as they are at present constituted. The attitude of many biologists and educationists towards biology teaching in schools leaves much to be desired. Their attitude can be ascribed to at least two things, namely, the lack of knowledge of the principles and importance of biology by those educationists, sociologists and even politicians who have had no training in the subject and also the attitude of a number of authoritative academic biologists themselves. This is evidenced to-day by the remark one is too often hearing that there is not much use for biologists as such in the war effort. How far this is true can be gauged from the successful formation and activity of the Biology War Committee (see Nature of Feb. 28, pp. 227 and 234). If biology can be utilized in this way in war-time, how useful then could it prove itself, given the chance in peace-time. Biology is not just botany plus zoology; it is the science of life, and if it is going to win the place in the educational system of the country which it deserves then it must be treated as such.

Mr. Brimble then gave one or two examples in more detail of how present-day biological teaching could be so modified as to make the science more interesting and useful and to bring it to bear more directly on the study of man and mankind. He did not plead for a complete reorganization of the syllabus, since the most important factor is the frame of mind of the teacher himself. The biology syllabus even if it remains unchanged is seething with opportunities for dealing with sociological implications.

Experimental work can also utilize man as a subject. There is a tendency towards this to-day but it could be taken much further with advantage. At the same time it would be dangerous to centre the biology syllabus completely around man himself because in a considerable number of aspects he is the exception rather than the rule. For example, the conception of the survival of the fittest would be very difficult to teach if man were the main centre of interest. The question of reproduction raises several important issues which must be faced by the teacher. There seems to be little doubt that human reproduction should be given its logical place in the biology syllabus but teachers must realize that it is a delicate subject and one which must be dealt with very carefully, preferably after consultation with parents. Mr. Brimble expressed the view that it would be better that the subject be omitted than dealt with clumsily.

Principles of social biology confront us at every turn in the school curriculum; for example, individual and public health, nutritional standards, housing, population movements, race and nation, problems of family life, relations and responsibilities of one person to another, social policy of the State. Make social biology an academic discipline; then it will follow that in later life our schoolchildren will give effect to it as citizens in public administration and national policy. How deeply involved social biology becomes in national policy was illustrated by Mr. Brimble in his comparison of the attitude of Fascist powers towards social biology with that of the democracies.

Dealing with the teaching of biology in the Higher School Certificate, Mr. Brimble emphasized the deplorable domination at this stage of the requirements of the universities. The same point of view was expressed by a speaker in the discussion on "Science in Post-War Schools" (see p. 459). At present Higher School Certificate biology centres around the requirements of the first M.B. examination and the university intermediate and scholarship examinations. There can be little argument in favour of this. Indeed it is in the Higher School Certificate that biology might be treated more directly as social biology, though Mr. Brimble stressed the desirability of approaching it as such throughout the school, having once based the general precepts of biology in the lower forms of secondary schools and in the junior and senior schools more on observational science—especially natural history. In the Higher School Certificate stage sociology, civics and citizenship are often taught, and the biology course could be brought into line with these subjects or perhaps even be absorbed by them. In fact, after the School Certificate stage, course of a year or probably two might well be based almost solely on cultural values. This, from the point of view of biology, was compared with remarks made by Mr. Hugh Lyon in his presidential address with reference to English.

In the discussion which followed, several valuable contributions were made, giving the general impression that the science master of to-day is anxious to emphasize more the social relations of the subjects he is teaching. Several speakers gave indications of what they were doing in their biological teaching along the lines discussed by Mr. Brimble. In the view of Mr. E. L. Walker (Caterham School), who gave several examples of his own teaching in social biology, there should be no difficulty in emphasizing the social impacts of biology. Mr. E. Lucas (Winchester College) also gave examples of his own methods and expressed the view that the social impact of biology should be brought out in the Higher School Certificate forms. Mr. Richard Palmer (lecturer in education, University of Liverpool, now seconded to the B.B.C.) made some very constructive remarks in favour of social biology and illustrated them with some excellent examples of what he and others are doing in school broadcasts. The method of teaching nutrition as practised by Mr. Palmer in school broadcasts followed closely those which Mr. Brimble would encourage; in fact Mr. Brimble used Mr. Palmer's method as an illustration of his own point of view.

Mr. Palmer and Mr. R. Weatherall (Eton College) did not agree with Mr. Brimble that man should not be treated as a central type. Mr. Bibby (Central Council for Health Education) made several valuable suggestions in favour of biology as a social science and expressed his disagreement with Mr. Lucas that social biology should be confined to the Higher School Certificate stage. Mr. Weatherall also expressed the view that Mr. Brimble's suggestions were too modest even at this stage, and considered that present-day biology teaching should be discarded in favour of social biology "from the cradle". Mr. Brimble replied that the course which he recommended teachers should adopt was probably not so modest as tactful. It is not possible in a democracy to get things done by revolution but rather by evolution, and he emphasized the fact that to put biology teaching on the basis which he and most of his audience desired depends chiefly on gradual modification of the teacher's attitude rather than wholesale discarding of the present principles and practice of teaching.

In his reply to Messrs. Palmer and Weatherall suggesting that man should be considered the central type, Mr. Brimble emphasized the pitfalls, giving the example of bacteriology. A knowledge of bacteria must come from a study of bacteria themselves and not from a study of man, otherwise there is the risk of giving the impression that bacteria only cause disease, whereas it should be remembered, of course, that there are as many useful and even essential types of bacteria as there are undesirable types. This can best be done by treating the bacterium as the type.

The general impression given by the discussion which followed Mr. Brimble's lecture was that teachers agree that biology should be treated more as a social science than it is, and that now is the time for educationists and teachers to approach the problem, since a golden opportunity is now at hand for making the subject of more comprehensive, cultural and therefore human interest.

Science in Post-War Schools

The discussion "Science in Post-War Schools" was opened by Mr. E. G. Savage, education officer to the London County Council, who was followed by Mr. S. V. Brown (Liverpool Institute). Mr. Savage foresees the danger that, at the end of the War, science in schools might be relegated to its previous position. He suggested that peace claims for science as the core of educational studies are even more exacting than those in war-time. Present curricula are conventional rather than rational, and both subjects and ways of teaching are dominated by examinations. He outlined seven aims of secondary education:

(1) Production of physical fitness and maintenance of health.

(2) Acquisition and practice of certain fundamental skills: speech, writing, calculation and capacity to think clearly;

(3) Production of qualities and development of aptitudes valuable in home life.

(4) Training for citizenship in a European democracy.

(5) Development of high ethical standards.

(6) Acquisition of knowledge and skills for proper use of leisure.

(7) Subjects as tools for probable vocations.

Mr. Savage examined the part which could be played by science teaching in all these aims.

Mr. Brown was more concerned with the work of the master. He pointed out that, of every hundred pupils who enter a secondary school, eighty-three take the School Certificate examination and sixty pass the examination. Fourteen enter for the Higher School Certificate of whom ten pass, and five, at the very most, go on to the university. He believes that what the teacher does, he does badly in the main, since he pays more attention to Higher School Certificate candidates than to the School Certificate forms; that the standard of a pass in School Certificate is too low, and that no pupil should sit for the School Certificate examination until he is at least 15½. The Higher School Certificate examination should be divorced from scholarship awards.

In the discussion which followed, many points of view were expressed. Nearly forty years ago Anatole France, an arch-apostle for Latin as the core of school-work, wrote: "Secondary education tends to strip itself more and more of that incomparable splendour which it derived from its apparent uselessness. Since such a transformation is necessary, since it corresponds to the change in customs, it is not very philosophical to lament it overmuch. Nations have an instinct for what suits them best, and the new France will doubtless find the teaching which her children need." France did not. Let us see that we do.

Atomic Structure in Chemistry

The chemistry discussion "Should an Outline of Atomic Structure be taught in the School Certificate Chemistry Course?", initiated by Mr. A. W. Wellings (Leamington College) and Dr. E. J. F. James (Winchester College), provided lively debate and stimulating discussion. It was evident that chemistry teachers are aware of the need of making the atom problem more rational, and appreciate the part to be played by chemical studies in a coherent scheme of science teaching, in giving, not the conceit of knowledge, but an intellectual humility that recognizes that all their pupils learn and do is primarily to open up fresh horizons.

Teaching of Physics

The joint discussion with the Physical Society on "The Teaching of Physics", with Prof. Allan Ferguson in the chair, was divided into two parts: (*a*) "Fundamental Laws and Definitions"; Mr. C. W. Hansel (Bedford School) tackled the problems of the concepts of mass and weight and the systems of units involved, already familiar in his papers to the Physical Society; (*b*) opening the second half of the discussion, Mr. P. Woodland (Bedford School) stressed "The Need for a Permanent Standardisation and Guidance Committee for Elementary Physics". The main objects of such a committee would be (i) to introduce such a measure of standardization of definition, statement of laws, notation and conventions as would save teachers, students and examiners much wasted effort, and (ii) to issue each year reports on the work done in physics in schools and similar institutions, and to give advice on any changes in syllabus or technique which might be helpful both to those concerned in the teaching or organization of physics and to those who employ students who have learnt physics for a vocational purpose.

Many members followed the opening speakers in both sections and some differences of opinion were evident. The constitution of such a committee proposed by Mr. Woodland and the ways of enforcing its recommendations were then examined.

Visits were paid to the British Thomson-Houston Co. and to the English Electric Co. The Members' Exhibition was one of the successes of the meeting. Such trends as could be discerned were in the greater attention given to alternating current, the production of wireless and aerodynamical apparatus for A.T.C. instruction and in the use of small-scale apparatus in chemistry. A valuable exhibition of scientific books and publications was well attended.

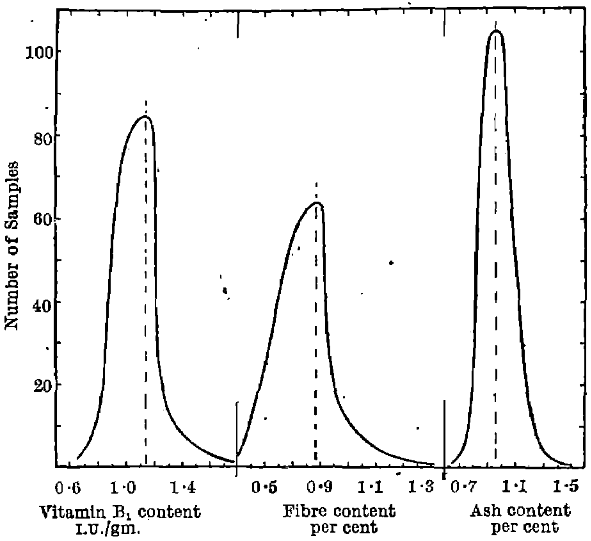
NATIONAL BREAD

By the Staff of the Research Association of British Flour-Millers

THE Medical Research Council in its second memorandum on bread[1] described in general terms the specification for 85 per cent National wheatmeal. It should contain 85 per cent of the weight of the clean wheat and in the case of a reconstituted meal should include all the white flour, all the reduction roll tails, mill finish and purifier tails and sufficient fine bran to reach the 85 per cent extraction figure. Analyses were given of meals prepared on the experimental plant in these laboratories, from which it was deduced that National meal should not contain less than 1 I.U. of vitamin B_1 per gm., and the fibre should not exceed 0·9 per cent.

The report further stated that improvers facilitate the work of the baker and lead to a more attractive loaf. Those normally used in the milling industry have been shown to have no effect on the vitamin B_1 content of flour or meal, and there is no evidence at present, on nutritional grounds, to justify their prohibition.

A few months ago the Ministry of Food arranged for a survey of the quality of the National wheatmeal being produced throughout Great Britain. Samples from more than 200 mills, large and small, were examined for vitamin B_1, fibre, ash, granularity and baking quality; in all, 303 samples have so far been examined, some of them being repeat samples from millers who had modified their methods.



Quality of Meals. The accompanying curves show the analytical results expressed as frequency curves. The modes and medians in the three curves correspond to the following figures:

	Mode	Median
Vitamin B_1	1·15 I.U./gm.	1·05 I.U./gm.
Fibre	0·85 per cent	0·70 per cent
Ash	0·95 ,,	0·95 ,,

Average figures for whole wheat are 1·3 I.U./gm., 2 per cent and 1·8 per cent respectively. The vitamin B_1 estimations were carried out by the thiochrome method[2] and could be duplicated with an accuracy of ± 5 per cent. The fibre was estimated by a method based on the Fertiliser and Feeding Stuffs Regulations 1932, with certain modifications. This method is routine in these laboratories and duplicate determinations on wheatmeals in general agree to within 0·05. The ash was determined on 5 gm. ignited in a muffle at 600° C., for six hours or overnight.

In view of the Medical Research Council's analytical criteria for wheatmeal, it is of interest to note that out of the 303 samples examined 253 had a B_1 content equal to or greater than 1 I.U. per gm. and 256 had a fibre content equal to or less than 0·9 per cent.

Quality of Breads. A meal conforming to analytical standards does not, however, always give a good loaf, and from the consumer's point of view the proper baking of National wheatmeal is just as important as its careful milling.

The absorption of each meal was determined by physical tests on doughs using special apparatus designed in these laboratories.

The moisture contents of the meals as received varied between 12·8 per cent and 16·1 per cent (5 hours at 100° C., in an electric oven):

18 per cent of the samples had moisture contents of 15 per cent or more
27 ,, ,, ,, ,, ,, ,, ,, ,, ,, 14½–15 per cent
28 ,, ,, ,, ,, ,, ,, ,, ,, ,, 14–14½ ,, ,,
27 ,, ,, ,, ,, ,, ,, ,, ,, ,, less than 14 ,,

The water absorptions varied between 14·9 and 17·8 gallons per sack.

This variation in absorption was only partly affected by the variations in moisture content, since when recalculated to a 14 per cent moisture basis it was found that:

8 per cent of the samples had absorptions of 17 gal./sack or more
32 ,, ,, ,, ,, ,, ,, ,, ,, $16\frac{1}{2}$–17 gal./sack
41 ,, ,, ,, ,, ,, ,, ,, ,, 16–$16\frac{1}{2}$,, ,,
14 ,, ,, ,, ,, ,, ,, ,, $15\frac{1}{2}$–16 ,, ,,
5 ,, ,, ,, ,, ,, ,, ,, ,, less than $15\frac{1}{2}$ gal./sack

The variations in absorption are due to differences in wheat grist, severity of milling (as affecting starch damage) and composition of meal.

Each sample was baked at its correct absorption, using 1 per cent yeast and a total fermentation time of 5 hours to the oven.

The great majority of the doughs handled satisfactorily, but the general quality of the bread was not so good. The most striking point was the number of samples with under-developed crumbs, indicating the lack of sufficient improver treatment. Wherever the size of the sample allowed, a repeat bake was made after the addition of further improver, and in almost every case the resultant bread was satisfactory, the crumb being fine-grained and smooth and the loaf better risen. It should, however, be pointed out that the samples were baked probably only a few days after milling and that their baking quality would have improved with increased age.

A few of the meals contained too much bran. In others the bran particles were too coarse: in such cases the crumb tends to be weak and friable and the bread is difficult to slice. By contrast, we have found that if the bran is too fine (of flour fineness) the loaf tends to be muddy in appearance. The loaf with the most pleasant crumb appearance has a clean background colour on which the fine bran particles are superimposed. The water content of National bread (crumb) is generally about 47 per cent, that is, about 3 per cent higher than white bread.

Some of the breads examined had weak crumbs devoid of spring. These samples had high maltose figures due probably to the inclusion in the grist of damaged English wheat from last year's harvest.

Milling and Baking National Wheatmeal

Milling. The basal objectives of the Medical Research Council specification were the maximum germ and aleurone layer and the minimum of fibre.

Precise milling technique to remove the aleurone layer cannot yet be laid down and in fact, even in the case of the factors of germ and fibre, it is difficult to formulate a general procedure. Broadly speaking, however, the *excluded* products in the milling of National wheatmeal should primarily be the scalpings of the last break, that is, the bran both large and small (including pollards), which will constitute a variable but preponderating part of the 15 per cent aimed at. The balance of the excluded 15 per cent should be filled with purifier tins (1 or 2 per cent), the small amount of aspirated stock and selected purifier tails. These latter differ widely in character, some being comparatively rich in endosperm material. Those incorporated in the 15 per cent 'reject' should be the most fibrous, and if careful visual inspection is insufficient, samples should be assayed for fibre to help in the selection.

Alternatively, the 85 per cent meal should *include*:

(1) All the white flour (say, 75 per cent).

(2) All the mill finish and reduction roll tails (say, 6–7 per cent).

(3) All the germ normally separated (say, $\frac{1}{4}$–$\frac{1}{2}$ per cent).

(4) Certain selected purifier tails (say, 2–3 per cent).

(5) If required to make up the 85 per cent, the appropriate quantity of fine bran or pollards.

Some typical figures for the composition of these factions have already been published[3].

The assumption is made here that the purification system is still run on usual lines. This is a point for further investigation, but provisionally it is felt that the continued use of the system may be found helpful in excluding as much as possible of the undesirable fibrous coatings from the meal. This will be particularly so if the feed to the break system is drier or harder than in the milling of white flour.

Experiments which will be described separately have shown that for good keeping qualities the moisture content of the finished wheatmeal should be approximately 14 per cent. Allowing a 1 per cent loss in moisture during milling, the moisture content of the mill feed should not exceed 15 per cent. This, however, is only one aspect of the problem, and further work is in progress on the more general problem, the influence of moisture content on the composition of the resulting meal. There is, however, evidence to show that with a drier mill feed there is a greater separation of aleurone layer from the bran.

It is definitely undesirable to pulverize the bran (through 10-silk), the reason being, as stated above, that the presence of bran powder gives a muddy colour to the loaf. On the other hand, coarse bran pieces (coarser than 24 w.) give a friable, unsatisfactory crumb. Between these limits we have no precise experimental evidence but are of the opinion that the smaller the bran fragments the better the loaf. The work of Macrae[4] has shown that the size of bran particle does not affect its digestibility.

With regard to germ, our experiments show that it is immaterial whether the pieces are large or small.

If the mill finish and reduction roll tails go into the meal as well as the flour, the question arises, is it worth while carrying on these reductions or could the stocks normally feeding the particular rolls go straight into the meal? To shut down these rolls would save power, wear and tear and operational demands; it would avoid some disintegration of offal. At the same time it would lead to some endosperm being present in the meal in a coarser condition than would otherwise be the case. This point also requires further investigation, but our present evidence indicates that the granularity of the endosperm is not an important factor in National bread.

Unquestionably the use of improvers is more important than with white flour, because the response of the germy and low-grade stocks to such treatment is very great. Generally the dosage should be at least 50 per cent greater than with white flour; the effect appears to be the same whether the white flour basis alone or the finished meal receives the treatment.

Breadmaking. In the past, brown bread has often been baked on very short systems using large quantities of yeast. This was feasible because of the relatively small quantities of such bread made, but now bakers will wish to make National wheatmeal bread on similar systems to those they have hitherto used for white bread.

Our experience with hand-made bread is that good quality National bread can be made on almost any system. As with white bread, the strength and soundness of the grist from which the meal is milled is a deciding factor in the quality of the bread, but in general a wheatmeal dough requires similar treatment to a white flour dough, that is, proper fermentation and correct handling. Any weakness in the grist or lack of correct fermentation or handling in the bakehouse will, however, be more apparent in wheatmeal than in white bread and, as has already been stressed, the need for correct improver treatment is particularly important.

To sum up, wheatmeal bread requires no real alteration to present-day baking methods, although for optimum quality bread greater attention to details, such as length of final proof, is desirable.

Conclusions

The survey showed that approximately 80 per cent of the mills were producing National meal conforming to the standards laid down in the Medical Research Council's specification. This survey was carried out when white flour, with its competing technical demands, was being milled.

There are a number of technical milling points which have to be investigated and explored before a meal, standard in all respects throughout Great Britain, can be produced. Equally, with greater experience of National wheatmeal, the bakers will be alive to the points requiring attention in order to produce National bread of the best quality.

It is of interest to note that the analytical criteria suggested by the Medical Research Council, namely, a vitamin B_1 content equal to or greater than 1 I.U. per gm. and a fibre content equal to or less than 0·9 per cent, apply on the commercial scale. In fact it may reasonably be expected that with appropriate modifications in the milling process, the fibre and B_1 figures will ultimately be improved still further.

MATHEMATICAL MACHINES

By DR. S. LILLEY,

St. John's College, Cambridge

Rise of Modern Arithmetic

IN 1585, when Simon Stevin, the Dutch canal and military engineer, published his little book[1]* advocating the use of the decimal system, he opened up a new era in arithmetic. He dedicated his work "To Astronomers, Land-meaters, Gaudgers, Stereometers in generall, Money-Masters, and to all Marchants....". If he had added to this list military and mining engineers and mentioned, as he does later, that the chief use of the astronomy was in navigation, he would have given a complete list of the social conditions which were calling out for the new arithmetic. For, as Hessen[2] has shown, the sixteenth and seventeenth centuries form a period in which capitalism, and especially merchant capital, was ousting the feudal economy in Europe and setting to natural philosophers a host of new technical problems—problems which formed the source of almost all the physical sciences of that period. It was to aid this new science, as well as to help the accounting of the merchants, that the new decimal system came into being.

Stevin's system was not actually new to the world, for its equivalent had been used by the Babylonians about 2000 B.C. But the social forces that brought about its rediscovery drove mathematicians to seek even better methods of computation. Thus in 1614 John Napier[3] published his logarithms. Without these, Kepler's computations and so Newton's "Principia" would have been impossible. It was to satisfy the same needs that the first attempts to construct calculating machines were made. Such were the machines of Pascal (1642), Morland (1666), Leibniz (1694), Leupold (1727), Stanhope (1775) and Hahn (1779)[4].

These machines between them contain practically all the devices that are used in modern "general purposes" (adding, subtracting, multiplying and dividing) machines. But though these men had the genius to conceive the basic principles, none of their machines was successful. The technique necessary to cut gears of sufficient accuracy and durability did not exist; the call for calculating machines was not sufficient to cause the technique to be developed for this purpose alone, and it was not until after the Industrial Revolution in Great Britain that a greatly increased demand for calculating machines, with a demand for mechanical efficiency in many other fields, gave sufficient incentive to force the solution of these technical problems.

The Industrial Revolution

The early part of the eighteenth century was a period of quiescence in the history of science. The scientific problems arising from the needs of mercantile capital had in the main been solved and it was not until the Industrial Revolution produced a demand for power, which could not be satisfied by the then existing means, that a revival took place—chiefly in problems arising from the steam engine, leading to thermodynamics, a subject which reached a reasonable degree of perfection about 1850.

Curiously enough, English mathematics did not keep pace with these scientific advances. Newtonian mathematics, representing essentially the needs of the older mercantile capitalism, was firmly established in the universities; the newer industrial manufacturing classes and the new sciences representing their needs had not yet succeeded in gaining a foothold there. In the early nineteenth century only one English university mathematician was facing the economic changes that were taking place and the revolution in mathematics that should accompany them. That man was Charles Babbage, Lucasian professor of mathematics at Cambridge. His book, "The Economy of Machines and Manufactures" (1832), must have seemed then a strange work for an academic mathematician, containing as it did a thorough analysis of the economic and technical aspects of the new industries. In "The Decline of Science in England" (1830), too, he shows a clear realization of the way in which the established scientific bodies (including the Royal Society) were degenerating, though he does not seem to have been really conscious that this degeneracy was a result of their lack of interest in the scientific problems which he so ably discusses in the other book.

It was this man, combining the tradition and educational advantages of an academic mathematician with a realization of the new fields that science must conquer, who made the next notable attempt to produce a practicable calculating machine. His two attempts were extremely ambitious[3,9,10]. First came his "Difference Engine", intended mainly for the construction of tables, the principle of which is briefly as follows: Consider, for example, a table of squares, beginning 1, 4, 9, 16, 25, . . . The first differences (that is, the differences between each number and its predecessor) read 3, 5, 7, 9, . . .; the second differences (differences of first differences) are 2, 2, 2, . . ., in fact, constant. Once this property has been observed, the original table may be extended by noting that the next first difference is $9 + 2 = 11$, and thus the next term in the table is $25 + 11 = 36$, etc. Thus we can calculate any number of terms in the table by addition only, instead of by multiplication, and similarly for other tables.

---

* References in this form are to the Bibliography at the end of the article.

Construction of the machine was begun by the Government in 1823, but the work was suspended in 1834, when £17,000 had been spent, and abandoned in 1842. The chief reason for the failure and for the enormous cost was the want of proper machine tools for the execution of the work—the necessary technique was still not developed. The modern National accounting machine[11] is essentially similar to the one Babbage planned.

Babbage's second machine, the "Analytical Engine", was even more ambitious. It was intended to tabulate by punch-card methods the values of any function for which a finite mathematical expression can be written. Although Babbage began work on this machine in 1834, the technical problems were too great and little progress was made. The modern counterpart of this "Engine" is the Hollerith punch-card machine[12].

First Successful Calculating Machines

With the possible exception of the Thomas de Colmar "Arithmometer" (1820), no successful calculating machine was produced until the 1880's, when the continually growing demand, coupled with the accurate machine tools which were now available, caused an extremely rapid development of many efficient machines. The Brunsviga, for example, first appeared in 1892, and twenty thousand had been made by 1912. The Comptometer, the first successful key-operated machine, appeared in 1887; and many other successful machines were made about the same period[3]. Since that time no fundamental change has taken place in the ordinary calculating machine, though a multitude of detailed improvements have greatly increased its speed and efficiency[5,6].

Any machine which performs the four fundamental operations of arithmetic can, of course, be used to solve any computational problem. But in many cases the process is likely to be too slow and tedious. It is for this reason that we find, again in the nineteenth century, especially the third quarter, and in the twentieth century, the appearance of large numbers of more specialized machines, each intended to solve rapidly and easily some particular type of problem the importance and frequent occurrence of which makes it worthy of this special attention.

To begin with, there are the National and the Hollerith, which have already been mentioned. The former has its chief application in the preparation of tables and has been extensively used in computing the "Nautical Almanac". The second is used, among other things, for statistical analysis and has been applied to agricultural statistics[12].

The Differential Analyser

Differential equations have formed an important part of mathematics from Newton onwards, but in the nineteenth century and especially towards its end, they became so important as to force scientific men seriously to tackle the problem of their solution. At first various instruments, "integraphs"[13] were produced for solving special types of equations, but these sink to insignificance beside Kelvin's proposal for the mechanical integration of any ordinary differential equation.

The principle of the disk-and-wheel or disk-sphere-and-cylinder integrator for evaluating $\int f(x)dx$ had been used since the early part of the century in various integraphs and planimeters. Essentially it is a continuously variable gear. If the gear ratio is $1 : f(x)$ and the input shaft turns through an angle dx, the output turns through $f(x)dx$. If now the input turns continuously representing the variable, x, while the gear ratio is connected with x in such a way as to describe $f(x)$, then the total angle through which the output shaft turns is $\int f(x)dx$. By mechanical interconnexion of such integrators, any ordinary differential equation can (in theory) be integrated. In 1876 Kelvin pointed this out in regard to linear differential equations[7].

But the mechanical difficulties were too great. The friction drive from disk to wheel does not give sufficient power to drive the further mechanical connexions that are required. Thus Kelvin was unable to produce a working model, and indeed this was not done until about 1931, when Bush solved the problem of the 'torque amplifier'[13,14]. The principle of the torque amplifier is extremely simple; it is essentially the same as the capstan of a ship. The capstan is kept rotating, a rope is wound several times round it, and it is found that a small pull on one end of the rope produces a much stronger pull on the other end. With this addition, Kelvin's ideas can be put into practice.

Importance of Wave Motion

Physics of the latter half of the nineteenth century is very much concerned with wave motion. Maxwell's electromagnetic theory is its greatest theoretical achievement, but its real basis lies in two subjects of vital economic importance, which very much occupied men's minds at the time—telegraphy and tides. The first practical trial of telegraphy took place on the London and North-Western Railway in 1837. The first successful Atlantic cable was laid in 1865, and many technical problems arose in this connexion. Thus the discussion of the nature of the wave-motion in the cable assumed the utmost importance.

Investigations of tidal phenomena date, for obvious reasons, from the earliest days of the mercantile capital period, and notable work on the problem was done by Newton, Euler and Laplace. All this work was of a synthetic nature—attempts to produce general formulæ to represent the motion of the tides. But a gradual accumulation of evidence showed that the problem was too complicated to be tackled in this way. Thus, when the British Association appointed a committee to deal with the matter, Kelvin was led to suggest (about 1876) the alternative *analytic* method, namely, to analyse the tidal curve at any one spot into its simple harmonic components, to extrapolate each of these into the future and to recombine them to give the tide at any assigned future time.

These two sets of problems lent great importance to the harmonic analysis and synthesis of wave-motion, and it was not long before many machines were produced to deal with this problem. By Fourier's theorem the problem of finding the harmonic components of a periodic function $f(x)$ is equivalent to that of performing a set of integrations $\int_0^{2\pi} f(x) \cos nx dx$, for $n = 0, 1, 2, \ldots$. In 1876 Kelvin pointed out that such integrations could be performed by an adaptation of the wheel-and-disk integrator, as described above. Many machines have been constructed on this or similar principles, the most important modification being the use of several integrators simultaneously, representing several values of n. The next few years brought many harmonic analysers; for example, those of Henrici (1894), Sharp (1894) based on the principle just outlined and of Yule (1895), Michelson and Stratton (1898), Mader (1909) and Boucherot (1913) on other principles[3].

More interesting, perhaps, is Kelvin's tide-predictor (1876)[3, 7]. In spite of its specific name, it is a machine for performing a synthesis of *any* system of harmonic components. It consists of a number of pulleys, conveniently arranged, each of which is given a harmonic motion. A wire, with one end fixed, passes over each in turn, and the other end then describes a motion which is the sum of the motions of the pulleys. Such machines are now in use in the navigation departments of several governments.

In recent times there has been a further outburst of harmonic analysers and synthesizers, such as those of Kranz (1927)[15], and Brown (1939)[16] based on the principle of the tide-predictor, and of Montgomery (1938)[17] using an optical method. The reason for this outburst seems to be the great crop of wave-motion problems arising from radio, the 'talkies' and quantum theory. Incidentally, by a simple mathematical trick, any harmonic synthesizer can be used as an analyser; it is very surprising that this does not seem to have been noticed before the 1920's.

Linear and Integral Equations

For reasons of space we can only refer briefly to two out of many other types of machines[8], though some of them are nearly as important as those described. The solution of sets of simultaneous linear equations is obviously an important problem, for example, in the theory of stresses in frameworks. Many machines have been constructed to solve such equations, for example, those of Kelvin (1878)[3,7], and Wilbur (1936)[19], working mechanically, and that of Mallock (1932)[18] on an electrical principle.

Just as differential equations describe, as it were, the point a system will reach, given only where it started and in what direction it is going, so also integral equations solve problems where the past history of a system is required to determine its present and future state. The importance of many such problems has recently grown enormously, for example, in hysteresis and in biological growth problems. Thus machines to evaluate definite integrals containing a variable parameter and so indirectly to solve integral equations are a recent development of considerable significance. They use optical methods[8, 20, 21].

Thinking in Terms of Machines

One of the reasons why mathematical machines were developed in the period after the Industrial Revolution rather than in the earlier merchant capital period was that the industrial period presented to the mathematician a much greater variety of problems which could only be solved within the given limits of space and time by the use of every available instrument. Another reason was that the Industrial Revolution had developed the necessary mechanical technique. To these must be added another reason, namely, the way in which men's minds had been altered by the circumstances in which they lived. Kelvin was in many ways the typical scientific worker of the latter nineteenth century, his activities ranging from what would now be called 'pure' research to detailed problems of applied technology and even to the application of his science as a very successful man of business, for he left a considerable fortune. Such men were used to thinking of the machine as typical of man's attack on the problem of living, and of a differential equation as representing the motion of a machine; and it was not difficult for them to reverse the process and make the machine represent and solve the equation. But to men of Newton's time a differential equation represented the motion of the moon or of a projectile, neither of which could be used conversely to solve the equation. Thus they were unlikely to think of machines as a method of dealing with their mathematical problems.

A similar ideological effect appears in the recent development of integral equations and machines for solving them. In the nineteenth century wave-motion must have seemed typical of the way of the world. It appeared in telegraphy and tides. But it also appeared as typical of history. The world seemed a more or less stable system; it had the wave-motion of the trade cycle, but it did not show obvious signs of a direction of development. But in the last two decades processes which were observed by only a few in the nineteenth century have become obvious to all. The world is changing; the old system is visibly breaking down and a new one is needed. Simple harmonic motion no longer adequately describes the world-machine, and the historical method of thinking becomes more and more necessary. It is in these circumstances that integral equations, the mathematical method of taking into account the history of a system, have so enormously developed. They arise from concrete problems, but it seems likely that the ideological background of a society in which history is so imminently visible has considerably helped their development.

Organization of Calculation

In spite of the headlong development of mathematical machines in the last seventy years, it remains unfortunately true that their vast potentialities are still largely unexplored. Many of these machines cost thousands of pounds to build. They cannot be constructed in order to solve a few problems. Yet there are many problems of such a nature that hundreds of workers all over the world meet half-a-dozen in a lifetime. At present that means to each of them many hours of laborious computing with a Brunsviga or even a slide-rule. An efficient organization with centralized laboratories to which all such problems could be sent would make it possible to provide machines to do this work in one-hundredth of the time and so would save the world many hours of valuable labour and enable the worker to spend his time more profitably than on handle-turning.

At least one attempt to provide a service in Great Britain on these lines has been established, on a business footing, and within its limitations has proved to be highly valuable. But such privately owned concerns may not be able to obtain all the more expensive and more specialized machines, which are at present mainly scattered throughout the laboratories of industrial companies, universities and similar institutions, where their use is practically restricted to members of the institution concerned. It would appear that the great possibilities of mathematical machines can be fully realized only through an organization supported by public funds, concentrating all types of machines under its care and using them to solve the problems of scientific workers wherever they may happen to be working. This must stand as not the least of the problems of social re-organization which confront the world to-day.

Future Trends

At present machine mathematics is widely regarded as being not quite respectable, not quite mathematics. This is especially the opinion of that school who see the chief justification of mathematics in what they interpret as its uselessness, combined with its "intrinsic beauty". Such mathematicians should take a warning from history. For theirs was the attitude adopted by English mathematicians of the eighteenth and three-quarters of the nineteenth century, with the result that, while Continental mathematics forged ahead, the English mathematician toyed with his "beautiful" problems of the Newtonian era, ignoring the fact that these had by then lost all relation to social usefulness and that the conditions of the Industrial Revolution were calling for new techniques. Thus it came about that Great Britain dropped far behind and had to be modernized with a jerk, when at last the scientific representative of the industrial capitalist burst into the universities, besides setting up his own research institutions.

There seems not to be a danger of this happening again. The real problems of to-day need machines, and machines have come to stay. If mathematics is to advance, it must recognize this fact and re-organize itself appropriately. This implies re-orientation in the light of the possibilities and the limitations of machines. To give one trivial example, in all machines so far in existence, the multiplication of two varying functions is an extremely awkward matter, while integration is comparatively simple. This suggests that our analysis should be 're-worded' so as to substitute integration for multiplication wherever possible. This, of course, may mean the loss of some formal elegance, but formal elegance must and will give way to the needs of practice.

NEWS and VIEWS

Manuscripts of Charles Darwin

We understand that the trustees of Charles Darwin are considering disposing of original MSS. of Darwin's which are in their care. These include the manuscript journal kept by Darwin during the voyage of the *Beagle* (1831–36) on which was based his "Journal of Researches into the Natural History and Geology of the various countries visited by H.M.S. *Beagle* . . .", Darwin's autobiography in his own handwriting with alterations made or suggested by Mrs. Darwin, the manuscript of "The Effects of Cross- and Self-Fertilization in the Vegetable Kingdom", the 1844 sketch of "The Origin of Species", and a large number of letters and miscellaneous material most of which has been published. Although this material may contain little of strictly scientific value, it has an obvious interest to the historian of science as revealing the workings of Darwin's mind at different periods of his life, and it would be unfortunate if the material should be dispersed. Such documents should be preserved in a library where access to them can be had by students, and it is to be hoped that some benefactor of science, aided perhaps by the Friends of the National Libraries, or some similar body, may be able to secure them for that purpose.

Future of Radio Communication

Captain P. P. Eckersley addressed the British Institute of Radio Engineers at its meeting on April 18 on "The Future of Radio Communication". He dealt at some length with the limitation of communication channels available, for the whole of

Europe for example, without mutual interference, and explained that, although the number of possible frequencies available might be infinite, the useful range is not. He said that the service range of transmission might be said to be proportional to its wavelength, so that very high frequency transmissions have a very small reliable service area. If the band width occupied by a transmission could be reduced, the number of channels could be increased in the same proportion. Examples of narrow band transmissions cited included single sideband, suppressed carrier (for wired transmissions) and restricted modulation frequencies, and he mentioned an American invention by which an intelligible modulation range of 200–3,000 c./s. can be transformed at the transmitter to a range of from zero to a few hundred cycles a second, thus reducing the sideband frequency width to be accommodated, and providing further channels in a given range of carrier frequencies ; the signal is re-transformed at the receiver. Captain Eckersley still believes, in spite of theories to the contrary, that sidebands were real.

Dealing with wired broadcasting, Captain Eckersley expressed the view that this system would provide a solution to ether congestion, and envisaged a future when perhaps even a special cable would be laid to every house, not only in Great Britain, but also in every country of the world, linking continents as far apart as Europe and America, although he realizes the present difficulties of operating a submarine cable of such dimensions. The number of channels available in a wired system would be infinite, and in this, together with the American invention described, he sees in the future a solution of our broadcasting problems.

Development of Fuel Research

On March 26 Dr. E. W. Smith, director-general of gas supply, Board of Trade, addressed the Fuel Luncheon Club of London, choosing as his subject the question : "What do we want ?" By "We" he meant the British community as a whole and not the interests of some particular industry or individual. He suggested that fuel, heat and power supply is more important than any other future concern of the Government, even than agriculture. Unrestricted competition, he said, should be abolished. The utilization of coal has led to our growth of industry and population, but the advantages so gained cannot continue indefinitely, and possibly not for long. To raise coal and sell it abroad at a loss is folly. To do the same with competitive fuels at home is equally foolish.

The Board of Trade has brought into one control coal, gas, electricity and oil, but if a Ministry of Fuel were established it should do more than regulate these. It should be a highly competent body, independent of vested interests, capable of advising, with long views, on the whole fuel policy of the nation. Fuel is becoming dearer and the mere stimulation of coal consumption is wrong. Allocation of fuel for domestic and industrial use should be made according to what has been determined as the best for a given purpose. This calls for a development of research on a great scale, greater than any hitherto known in Great Britain. Fuel research should no longer be distributed among many competitive research organizations, but co-ordinated in one comprehensive scheme with directors of the specialized branches. It should then be done with the most ample and best-equipped facilities for experiment.

Statistical Theory of Accident Proneness

The scientific investigation of industrial accidents may be regarded as commencing in 1919 with the publication of a report by Prof. Major Greenwood and H. M. Woods for the Industrial Health Research Board, then known as the Industrial Fatigue Research Board, the data in which indicated that the hypothesis that persons were different in their liability to accidents from the start gave the best fit to the observed distributions. The mathematical considerations underlying these theoretical distributions were examined by Prof. Greenwood and Mr. Udny Yule in a paper published in the *Journal of the Royal Statistical Society* in 1920. A further paper on theory and observation in the investigation of accident causation by E. G. Chambers and G. Udny Yule has now appeared in the supplement to the same *Journal* (7, 89–109 ; 1941). In this, Mr. Yule gives a note on the statistical theory of accidents with special reference to the time factor, application of which to accident data leads to the conclusion that a lengthy period of experience is necessary for an individual proneness to accidents to manifest itself fully. Accident proneness may be regarded as a latent disposition needing certain circumstances to reveal it, rather than as an active function which is constantly in operation. Individual differences in accident proneness may, therefore, play their part chiefly in the earlier period of exposure to risk, their importance diminishing as the period of exposure increases. The maximum benefit gained by selective tests for proneness is, therefore, likely to accrue when the tests are applied to new entrants into risky occupations. The chief contributors towards accident rate might thus be found and eliminated during their most vulnerable periods. This conclusion is supported by the observed fact that selective tests are of much less value when applied to experienced workers than they are when given to new entrants.

To the discussion on this paper Dr. J. L. Irwin contributed an analysis of variance leading also to the conclusion that the most likely explanation of the differences between drivers is a difference in individual proneness to accidents, and Prof. Greenwood, commenting on the fact that Mr. Chambers had shown that a necessary condition for accepting the proneness hypothesis as a complete explanation of the fact is not fulfilled, agreed with his suggested explanation that the rate changes with time and pointed out that the study of Royal Air Force accidents might be of value here, since the high standard of selection probably eliminated the pathologically prone.

Fluorescent Light Sources

In a paper before the Illuminating Engineering Society on April 14, Mr. J. N. Aldington pointed out that two types of fluorescent lamp have been developed within the last decade, both of which employ the mercury vapour discharge as the source of primary radiation. In the first type, envisaged so long ago as 1900 by P. Cooper Hewitt, a high-pressure mercury arc operates with a high luminous efficiency, and fluorescent coatings on the outer bulb containing the arc tube produce colour modulation of the emitted light. Ultra-violet and violet radiation of a wavelength above about 3,000 A. is absorbed by suitable inorganic sulphides and is re-emitted in the visible region to supplement the dominant mercury light. The change in overall efficiency brought about by this energy transformation is negligible, but the effect on the colour-rendering properties of the emitted light is appreciable and useful. The second type of fluorescent light source is exemplified in the 80 watt MCF/U lamp, which was put on the market in March 1940, and is being used extensively for industrial lighting. A fluorescent powder layer coated on the inside surface of the tube containing a low-pressure mercury discharge tube is so vigorously excited by the resonance radiation from mercury that it produces about ten times the light given by an uncoated tube of similar size. The light is white and has colour-rendering properties sufficiently close to those of daylight for most industrial applications. The fluorescent layer is a mixture of inorganic powders which if used separately would give blue, yellow and red light and they are most efficiently activated by radiation of wave-length 2,537 A.

As the 80-watt lamp was designed primarily for industrial lighting to meet the demands of war-time conditions, the major applications in Great Britain have been in industry. Much experience has, however, been gained in the United States, where in the last three years fluorescent lamps have been introduced into practically every lighting field. It is found that the low surface brightness of approximately 0·5 candle per sq. cm. in the case of the 80-watt lamp and the large size of the source render it of great value for producing illumination conditions which can be made to approach daylight interior lighting. Shadows are softened and in a well-designed installation the illumination of vertical planes can be made effectively. In most cases stroboscopic effects are of little importance, the phosphorescence of certain of the powders used in the lamp construction assisting in bridging the gap between the cyclic changes in light output. The psychological effect of apparently cool light has proved advantageous in certain industries, and the freedom from glare in a well-designed installation is a noteworthy feature.

A Projected Canal System for England

In a booklet entitled "The Projected Grand Contour Canal" (Birmingham: Cotterell and Co., 2*s*.), Mr. J. F. Pownall describes his ideas of a waterway linking together the main ports of England and accessible to coasting vessels up to 1,500 tons displacement, as well as canal barges. He points out that in the main watersheds of England, the lowest cols are at approximately 300 ft. As a result, he plans this canal to follow as near as possible the 310 ft. contour, which would obviate canal locks, with their delay and cost of upkeep, and necessitate only a few tunnels. Already some two hundred miles of existing canals lie at about 300 ft.; others are at lower levels. These might be linked by lifts, which have the advantage over locks in that they do not lose water in operation.

The main canal and its chief branches would be 864 miles long and would be 100 ft. wide at the water level, 17 ft. deep, with a clear headway under bridges of 80 ft. From London the Lea navigation would be used and improved as far as Hertford, where the new canal would begin with a lift. Thence it would pass through Bletchley, Rugby, Lichfield and Market Drayton to Manchester, with branches to Birmingham, the Trent and Wrexham. Through Lancashire it would pass by Clitheroe and Skipton, with a branch to Bradford and the Aire and Calder navigation, and thence along the eastern flank of the Pennines to Richmond and Newcastle, with a branch to Hartlepool. In the south, branches would reach Bristol and Southampton. At or near all the great ports, lifts would operate to and from the 310 ft. level. Sixty per cent of industrial England would thus be served at a cost which Mr. Pownall estimates at a halfpenny per ton mile. Other features of the suggested canal would be its service as a 'water grid' and as a line for gas, oil and other pipes which could be laid on its bed.

Wood Pigeon Nest Census

An ecological survey of the wood pigeon's breeding habitats in Great Britain is being organized by the Edward Grey Institute, Museum Road, Oxford, as part of the British Trust for Ornithology's investigation into the biology of this species. The basis of the survey is a punch card, one being used for each occupied nest. The card is printed with a simple system of habitat classification; types of wood are illustrated by stating the name of the chief tree, shrub and flower. The finder also gives details of the position and contents of the nest, completing the hatching and fledging records if there are opportunities of returning to the nest. A punch card may be used at any time when a nest is found, but the maximum information is obtained from a census of any area of known acreage. If possible the census is repeated each month, cards being made out for nests not previously discovered and fresh information added to the old ones. The scheme is therefore flexible, allowing contributions from either an individual with only a few minutes to spare, or from members of a team; it also allows scope for organization within the team, encouraging those with specialized knowledge, such as a botanist, photographer, 'surveyor', and so on. For those proposing to organize a team census a pamphlet "How to Organise a Wood Pigeon Nest Census" is available from the Institute.

As the most active members of the Trust are now serving with the Forces a special appeal is being made to schools and youth organizations to help with the census. Several biology teachers are now using pigeons in dissection classes, and are studying crop contents, checking their identifications with observations in the field. A leaflet "Directions for Biologists" is available for anyone willing to undertake the examination of pigeons.

Lodgewood Telegraph Poles

C. H. Amadon, in an article on this subject (*Bell Lab. Rec.*, 20, No. 6, Feb., 1942), refers first to initial experiments made to preserve pine poles by creosoting, and secondly describes the method finally adopted. In the latter the poles are placed in closed cylinders and compressed air is admitted for about half an hour until the pressure rises to about 85 lb. per sq. in. Some of this air enters the cells of the wood. Hot creosote is then pumped in until the cylinder is full, pressure being maintained at 85 lb. per sq. in. during this period. More hot creosote is next pumped in until the pressure rises to about 135 lb. per sq. in. During this period of nearly three hours the creosote is taken up by the wood and fills its cells. At the end of this pumping period, air pressure is released and a vacuum is created under which the entrapped air brings to the surface most of the excess creosote, which drips off and is pumped out of the cylinder. The vacuum is broken after about an hour and live steam at a pressure of 20 lb. per sq. in. and a temperature of 260° F. is admitted to the cylinders and maintained for three hours to re-establish pressure in the wood and increase the fluidity of the remaining creosote. A vacuum is then drawn again and held for an hour, during which time more of the creosote comes to the surface and drips off. The vacuum is then broken and the cylinders are opened. Any liquid creosote on the surface of the poles is quickly reabsorbed, and the poles are reasonably clean. The first charge treated in this way completely satisfied all requirements. Approximately 50,000 full-length pressure-creosoted lodgepole pine poles have been treated according to the process described, with a high degree of conformity to the desired results in terms of penetration, consumption of creosote and cleanliness of the poles.

X-Ray Reflexion and Scattering with Frequency Change

Theory and experimental work on the quantum reflexion and quantum scattering of X-rays are dealt with by Sir C. V. Raman in two papers (*Proc. Roy. Soc.*, A, 179, 289 ; 1942). The quantum or modified scattering is due to the excitation of the elastic solid or low-frequency vibrations of the crystal lattice by the X-ray photon. It has a very low specific intensity proportional to N (the number of lattice cells) and is distributed over a wide range of solid angles. The quantum or modified reflexion is due to the excitation of the infra-red or characteristic high-frequency vibrations of the crystal lattice by the X-ray photons. Its intensity, like that of the classical or unmodified reflexions, is of the order N^2, though usually smaller in absolute value than the intensity of the classical reflexions. The frequency changes which play a fundamental part in the theory of both phenomena appear as necessary consequences of both the classical and quantum theoretical points of view, but the law of intensity variation with temperature is quite different in the classical and quantum formulations. Experimental studies at low temperatures are specially important for the differences between the two theories. The influence of the modified X-ray reflexions on the intensity of the classical reflexions and their variation with temperature are discussed and shown to be of even greater importance then the effect on the same of the X-ray scattering by the elastic solid vibrations. In the second paper experimental results on diamond are reported agreeing with the theory.

An Improved Capacitance Bridge for Precision Measurements

To meet the demand for increased precision a new standardizing capacitance bridge, known as the No. 12 type, has recently been developed by the Bell Telephone Laboratories and is now described by W. D. Voelker (*Bell Lab. Rec.*, 20, No. 5 ; 1942). This bridge, operating at frequencies up to 200 kc., has a range of from 0 to 1·11 μF., and from 0 to 1000 μmhos. It is of the equal-ratio-arm type, the arms being of woven-wire resistance. A slide wire at the junction of the two resistances and an air condenser that allows capacitance to be shifted from one arm to the other, permit a small amount of adjustment that may be required at infrequent intervals to offset the effects of ageing. The resistances form the adjacent ratio arms of the bridge, and permit an unknown capacitance in a third arm to be measured against an adjustable standard capacitance in the fourth. This is the basic principle of the bridge. Conductance standards are included in the bridge. For measuring the larger values of capacitance silvered-mica condensers are employed as standards, while for smaller values of capacitance, air condensers are more convenient. The air-condenser standard consists of three decades of fixed capacitance and a movable plate condenser for fine adjustment. The control dial is calibrated to indicate directly the capacitance of the unknown for each position of the dial.

Medical Services in Sweden

The March issue of the *Anglo-Swedish Review* gives an interesting account by Torsten Trietz of the organization of medical services in Sweden. Preventive medicine is administered by public health officers, of whom there is one in each of the twenty-four counties and larger cities. Outdoor medical treatment is provided by the following groups of physicians : (1) in the provinces the district doctor is a State official appointed for the medical care of the population in rural districts, who receives a fixed salary and retiring allowance ; (2) urban physicians, who are also salaried physicians but are paid by the municipality ; (3) private practitioners who are also paid a salary. Owing to their social importance tuberculosis and venereal diseases are compulsorily notifiable and free treatment is provided. There is a panel service national health insurance, of which the cost is borne partly by the State and partly by the fees of the insured. The public indoor service is mainly provided in general hospitals and is administered by the county councils or municipal councils, and paid for by the taxpayers. The hospital treatment of tuberculosis is organized in sanatoria, of which there are about 100 with about 8,000 beds. Care of infectious diseases in fever hospitals is compulsory for certain diseases and is free. Radiological treatment of malignant growths and similar diseases is organized in special cancer clinics at Stockholm, Gothenburg, Lund and Uppsala. All indoor relief of mental cases is administered by the State in some twenty hospitals containing 17,000 beds. The nurses in Sweden receive three years training in the larger hospitals in co-operation with the Swedish Red Cross. Midwives are trained at two colleges, and treat the vast majority of cases of childbirth.

Courses of the Lower Ganges

The November issue of *Science and Culture*, which is conducted by the Indian Science News Association with the aim of advocating the application of scientific knowledge to the national welfare of India, contains an interesting article on the antiquity of the Lower Ganges and its courses. Mr. N. K. Bhattasali approaches the subject from the historical point of view. Little that is very definite emerges from Mahabharata and Pauranic literature, though a certain amount of evidence as regards the various mouths of the river suggests relatively few major changes. Ptolemy in A.D. 150 gave a full account of the Lower Ganges, and Mr. Bhattasali finds that, allowing the necessary corrections for Ptolemy's longitudes, the five mouths of the river are in approximately the same longitudes to-day as about nineteen hundred years ago. There are several maps in the article, including Rennell's map of 1761 and van den Broucke's of 1660.

Agricultural Scholarships

THE Ministry of Agriculture and Fisheries is offering for award, under its scheme of scholarships for the sons and daughters of agricultural workmen and others, a limited number of agricultural scholarships. The scheme was suspended following the outbreak of war but has been resumed this year in a modified form, and the Ministry invites applications for the following scholarships: ten senior scholarships, tenable at agricultural colleges or university departments of agriculture, for diploma or degree courses in an agricultural subject or at veterinary colleges for courses in veterinary science; thirty junior scholarships, tenable at certain farm institutes or similar institutions, for courses not exceeding a year in duration, in agriculture, horticulture, dairying, or poultry husbandry. The scholarships are open to the sons and daughters of agricultural workmen or of working bailiffs, smallholders and other rural workers whose means and method of livelihood are comparable with those of agricultural workmen, and to persons who are themselves *bona fide* workers in agriculture. Further information concerning the scheme, and forms of application, may be obtained from the Secretary of the Ministry, Hotel Lindum, St. Annes, Lytham St. Annes, Lancs.

Recent Earthquakes registered at Kew

BETWEEN March 8 and April 7, four large earthquakes were registered at Kew Observatory. The first, on March 8, started recording at 04h. 56m. 35s. U.T., had a maximum of 32 μ at Kew at 05h. 14m. 26s. U.T. and finished recording at 06h. 30m. U.T. It may have started at an epicentral distance of 3,900 km. The second, on March 19, began recording on all three components at 12h. 19m. 42s. U.T., had a maximum of 17 μ at 12h. 42m. 12s. U.T. and finished recording at 13h. 50m. U.T. The third, on March 21, began recording at 23h. 33m. 38s. U.T., possibly from an epicentral distance of 10,200 km., had a maximum of 155 μ at 22d. 00h. 19m. 37s. U.T., and finished recording at 02h. 15m. U.T. This shock was also well recorded at Stonyhurst. The fourth was on March 22. It began recording at 02h. 17m. 18s. U.T. from a possible epicentral distance of 6,700 km. and finished at 03h. 50m. U.T.

Earthquake of April 8 in the Philippines

IN NATURE of April 18 reference was made to an earthquake of considerable severity (probably submarine) in the neighbourhood of the Philippines on April 8. This shock and two smaller aftershocks were recorded at Bombay. The Rev. J. P. Rowland, S.J., obtained a beautiful record of this earthquake on the Milne-Shaw seismograph at Stonyhurst College Observatory. The tentative readings of this seismogram tend to support an epicentre near the Philippines as suggested by Riverview. The shock began recording at Stonyhurst on April 8 with i at 15h. 58m. 00s. U.T., had a maximum at 16h. 34m. 30s. U.T. and finished recording at 18h. 31m. U.T.

The Association of Scientific Workers

THE Association of Scientific Workers is holding its annual council meeting during May 2–3 at the London School of Hygiene and Tropical Medicine, Holborn, W.C.1. The Association has increased its membership from two to more than five thousand in the past year and has recently been affiliated to the Trades Union Congress. The main items for discussion will be the ways in which scientific workers and engineers can aid war production, and the need for improved professional status and educational facilities.

Following upon a memorandum from the Central London Branch of the Association of Scientific Workers, the Executive has set up a provisional Medical Sciences Committee "to further the objects of the A.Sc.W. among scientific and technical workers concerned with the medical and ancillary sciences". The provisional Committee has the immediate task of bringing together all members working in this field, as well as people anxious for the best application of knowledge in their place of work and for the war effort in general. The first meeting will be held on May 9 at 3 p.m. in the Small Conway Hall, Red Lion Square, W.C.1. Further information can be obtained from Dr. J. H. Humphrey, 32 West Hill Court, Millfield Lane, London, N.6.

Night Sky in May

FULL moon is on April 30d. 21h. 59 m. U.T. and new moon on May 15d. 05h. 45m. Full moon occurs on May 30d. 05h. 29m. Lunar conjunctions with the planets occur as follows: Venus on May 11d. 07h., Venus 0·6° N.; Mercury on May 17d. 04h., Mercury 7° N.; Jupiter on May 17d. 20h., Jupiter 5° N.; Mars on May 19d. 13h., Mars 6° N. Mercury, Mars and Jupiter are evening stars, and Saturn is also an evening star until May 23, then a morning star. Venus is a morning star and rises about 3h. in the middle of the month. Mars, Jupiter and Saturn can be observed in the evening hours, but Saturn is too close to the sun to be observed well. Mercury is in conjunction with Saturn on May 5d. 10h., Mercury 3·8° N. The chief occultation occurs on May 16d. 11h. 35·8m. when α Tauri disappears, reappearance taking place at 12h. 55·9m. The Aquarid meteor shower is active during May 4–11. The radiant is close to η Aquarii about the middle of the period of activity of the shower, which is associated with the debris of Halley's Comet.

Announcements

We regret to announce the death of Prof. Jean B. Perrin, For. Mem. R.S., formerly of the Faculty of Sciences at the Sorbonne, Paris, at the age of seventy-one, on April 17.

MAJOR HARRY G. ARMSTRONG, in charge of research at the United States School of Aviation Medicine at Randolph Field, Texas, has been given the John Jeffries award of the American Institute of the Aeronautical Sciences in recognition of his researches in the physiological and psychological effects of flying at high altitudes and in high-speed manœuvres.

THE Nutrition Society is planning a whole-day conference on "Problems of Collective Feeding in War-time", to be held at the London School of Hygiene and Tropical Medicine, on Saturday, May 30, beginning at 11 a.m. Further information can be obtained from Dr. Leslie J. Harris, Dunn Nutritional Laboratory, Milton Road, Cambridge.

CAPTAIN L. F. PLUGGE, M.P., chairman of the Parliamentary and Scientific Committee, recently wrote to Dr. Hugh Dalton, president of the Board of Trade, about the clothing needs of scientific research workers and chemists. In his reply, Dr. Dalton said that research workers who require only a few overalls in the course of a year will not get extra coupons; an award to be made early next month will, however, provide for those who needs are really very heavy.

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

The X-Ray Microscope

IN NATURE of April 22, 1939, I described an optical method of summing a double Fourier series, and so of producing an image of a crystal structure. To get a projection of the structure in a direction parallel to the b axis, for example, holes are drilled in a brass plate in the positions of cross-grating spectra. Each X-ray reflexion *hol* is represented by a hole the area of which is proportional to F (*hol*). When a parallel monochromatic beam passes through these holes, and then through a lens, the Fraunhofer fringes build up an image of the crystal structure which can be viewed through a microscope. Since a wide range of holes is required, and they are one or two millimetres apart, the smallest holes must be very fine. I am indebted to Dr. E. W. Fish for supplying me with a series of minute drills.

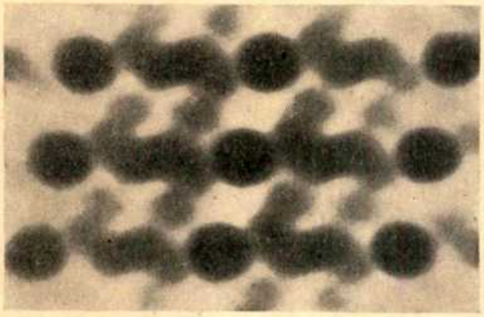

Fig. 1.

INTERFERENCE PATTERN (DIOPSIDE)

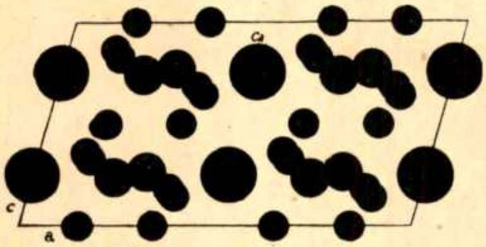

Fig. 2.

STRUCTURE OF DIOPSIDE, $CaMg(SiO_3)_2$, PROJECTED ON (010).

The present note describes certain simplifications in this method, and improvements in the perfection of the image. In the first place, we have found it possible to use a photographic reproduction of a diagram representing the cross-grating spectra in place of the plate drilled with holes. The paths of the waves issuing from the holes must be true to a fraction of a wave if the method is to work. To achieve this, advantage has been taken of one of the filmless photographic processes developed by the British Scientific Instrument Research Association. A drawing of the cross-grating spectra (represented by black dots of appropriate size) is photographed on a much reduced scale on a special type of plate. I am deeply indebted to Mr. A. J. Philpot, director of the Association, and Mr. Haigh, for making these reproductions for us. The black spots become transparent holes in the reproduction, and as there is no film over these holes and an optically true glass plate is used, the conditions for interference are satisfied. These photographs are much more perfect than the series of holes in a plate, and there is no restriction upon the complexity of the drawing.

Fig. 1 shows a photograph of an interference pattern representing diopside, $CaMg(SiO_3)_2$, the structure used to illustrate the method in the former note. This photograph was obtained with one of the plates prepared for us by the B.S.I.R.A. If it is compared with the former photograph, the considerable improvement in definition and extent of the pattern will be obvious. In Fig. 2 a diagram of the structure obtained by X-ray analysis is shown for comparison with the optical image, the atoms being represented by black dots.

In the case of diopside, F (*hol*) is positive for all values of h and l except (202). In the general centro-symmetrical case, both positive and negative values occur, so that a retardation to a path-difference of $\lambda/2$ must be introduced at the appropriate holes. We have found that this can be realized for two holes by cutting a half-wave plate of mica into small squares. To introduce a difference of $\lambda/2$, mica squares are placed one over each hole but with their fast axes at right angles. It is not necessary to polarize the light. This method might be extended to many holes, but the technical difficulties are rather considerable. It should be emphasized that the difficulties arise because path-differences must be right to a fraction of a wave; hence the squares must be cut from an extremely uniform mica sheet.

In making a Patterson synthesis, F^2 values are used and all coefficients are positive. Fig. 3 is an enlarged contact print of a B.S.I.R.A. plate representing the F^2 values of a horse methæmoglobin crystal measured by Perutz[1]. Fig. 4 shows the Patterson synthesis obtained by optical interference using this plate. The pattern on the photograph corresponds in detail to the distribution of maxima on the contour map obtained by calculation (see Fig. 5). Although the phases are all positive and thus present no trouble, another technical difficulty is encountered in the case of Patterson syntheses by interference. The constant term is large compared

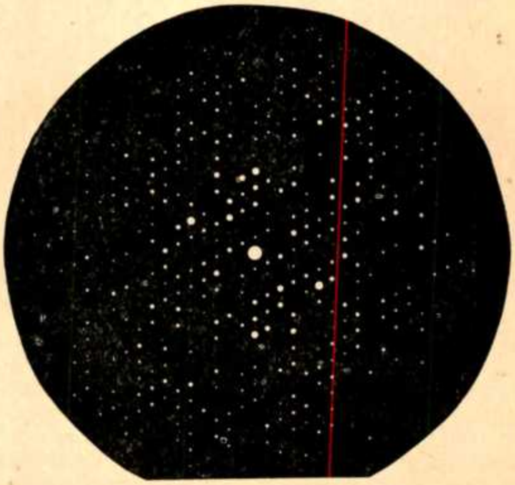

Fig. 3.

PRINT OF B.S.I.R.A. PLATE, HÆMOGLOBIN SPECTRA.

with the coefficients F^2, and hence the central hole has to be much larger than the others. On the other hand, it must be so small that its first diffraction fringe falls well outside the central cell of the pattern, since the reproduction is only true inside the central diffraction maximum. In the present case this maximum is made to cover one complete repeat of the Patterson pattern by making the diameter of the central hole less than half the distance between neighbouring spectra. This requirement sets the scale for all the spots in Fig. 3. The method promises to be useful for the rapid summation of Patterson-Fourier series.

PATTERSON INTERFERENCE PATTERN (HÆMOGLOBIN).

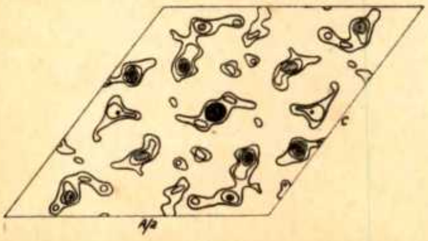

Fig. 5.
PATTERSON SYNTHESIS BY PERUTZ, TO BE COMPARED WITH FIG. 4.

When taking photographs of the images, we have found it advantageous to use a filter to select monochromatic light from a mercury vapour lamp, and to place the panchromatic plate so as to receive directly the image formed by the microscope objective. The exposures are of a few minutes duration. If the photographs are made in a camera attached to the eyepiece of the microscope, exposures of several hours are required and the images are less perfect. I wish to express my thanks to the General Electric Company for the gift of the lamp used for this purpose, and to my assistant Mr. Crowe who has taken the photographs.

W. L. Bragg.

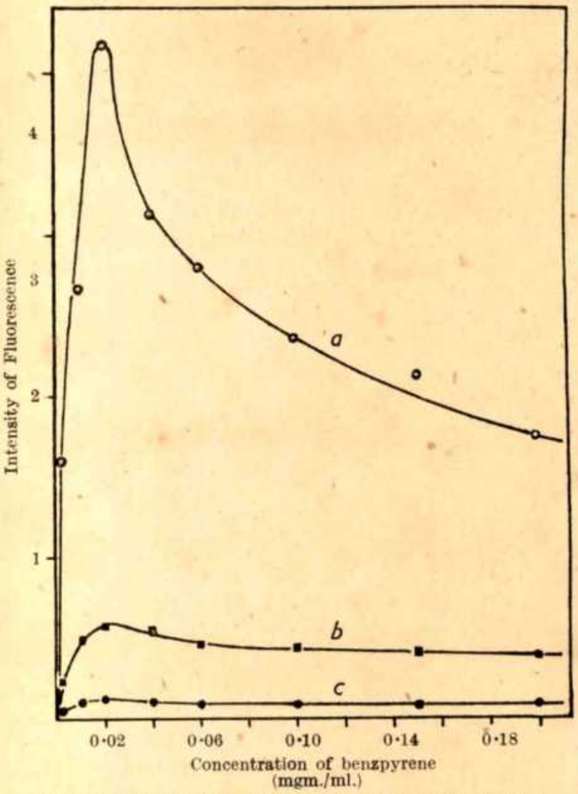
Reversible Quenching by Oxygen of the Fluorescence of Polycyclic Hydrocarbons

During an investigation into the estimation of 3 : 4-benzpyrene by fluorescence measurements, great differences in fluorescence intensity were observed according to the solvent used; for example, the fluorescence is about five times as intense in tetraline as in hexane. These differences were found to be entirely due to a quenching effect of dissolved oxygen. In the absence of oxygen, the fluorescence intensity curves of a series of benzpyrene concentrations are practically identical in all the solvents studied. The most striking feature of the quenching by oxygen is its complete and instantaneous reversibility. The fluorescence of a given solution which has been almost completely quenched by oxygen is immediately and completely restored to its original value if the oxygen is pumped off, and this cycle can be repeated indefinitely.



FLUORESCENCE INTENSITY OF 3 : 4-BENZPYRENE IN HEXANE SOLUTION
(*a*), *in vacuo*; (*b*), in air; (*c*), in oxygen at 1 atm. pressure.

In the accompanying graph the intensity of fluorescence (in arbitrary units) of 3 : 4-benzpyrene in hexane solution is plotted against its concentration for vacuum, air and oxygen of 1 atm. pressure. In the latter case the quenching amounts to about 97 per cent. At very low concentrations of benzpyrene the (unquenched) fluorescence increases almost linearly with concentration due to the correspondingly increasing light absorption in this region, whereas at higher concentrations the fluorescence yield decreases, obviously due to a 'self-quenching' effect.

A quenching effect by oxygen has previously been observed by Bowen and Norton[1] for solutions of anthracene in various solvents, and by Kautsky[2] and

Franck and collaborators[3] for chlorophyll solutions. In these cases, however, the effect is much smaller. The accompanying table shows the result of measurements with polycyclic hydrocarbons (some of them carcinogenic) and some other fluorescent substances under comparable conditions. Wherever a quenching effect of oxygen was observed, it was completely reversible.

PERCENTAGE QUENCHING OF FLUORESCENCE BY OXYGEN AT 1 ATM. PRESSURE IN ETHANOL SOLUTIONS CONTAINING 0·01 mgm./ml.

Anthracene	60·0
Chrysene	85·7
Pyrene	87·7
Rubrene	68·0
1 : 2-Benzanthracene	86·3
9 : 10-Dimethyl-1 : 2-benzanthracene	86·7
1 : 2 : 5 : 6-Dibenzanthracene	88·2
3 : 4-Benzpyrene	91·7
20-Methylcholanthrene	86·6
Ethyl chlorophyllide	32·1
Eosine	0
Thiochrome (in *iso*-butanol sol.)	27·5
Quinine sulph. (in 0·1 N H_2SO_4 in methanol ...	17·5
Acridine " " " "	0

Every elementary process of quenching is represented by a chemical reaction. The well-known ability of the polycyclic hydrocarbons to form photo-oxides[4] suggests the following primary process:

$$(HC)^* + O_2 \rightarrow (HC)^+ O_2^- \rightleftharpoons (HC)O_2,$$

where the optically excited hydrocarbon molecule $(HC)^*$, which has a lower ionization potential, transfers an electron to the oxygen molecule, thereby forming the photo-oxide, which is partially ionic in its character[5]. This process, which is reversible, suggests a type of reversible oxidation-reduction of the hydrocarbon.

It seems that the 'self-quenching' which is observed at higher concentrations of the fluorescent substance can be interpreted by an elementary process:

$$(HC)^* + (HC) \rightarrow (HC)^+ (HC)^- \rightleftharpoons (HC)_2,$$

where the excited hydrocarbon molecule $(HC)^*$ reacts with an ordinary molecule (HC), eventually leading to a dimer. It has been shown[6] that anthracene solutions give di-anthracene on irradiation, and it is suggested that in the case of benzpyrene (and other fluorescent substances where self-quenching occurs) a similar dimerization takes place under the influence of light which in general is reversible in the dark. This is supported by our observation that in this region the fluorescence yield can often be represented by the common hyperbolic equation if the total concentration of the hydrocarbon in solution is substituted for the concentration of the quenching substance.

We are greatly indebted to Dr. F. Dickens for many valuable discussions, and to Prof. J. W. Cook, who supplied some of the hydrocarbons used.

A New Salmonella Type

A NEW Salmonella type has been isolated by us from the mesenteric gland of a normal pig. It ferments, with the production of acid and gas, glucose, mannitol, arabinose, dulcitol, rhamnose, trehalose, sorbitol, lævulose, mannose, galactose and xylose; and does not ferment lactose, sucrose, adonitol, erythritol, inulin, raffinose and salicin. It is indole-negative and H_2S-positive, reduces nitrates to nitrites and does not hydrolyse urea; in Stern's medium it is positive; in Bitter's medium it is positive with glucose, arabinose and rhamnose, and negative with dulcitol; on Simmons' agar it is positive with glucose, arabinose, dulcitol and rhamnose; it does not liquefy gelatine and is *d*-tartrate-, *l*-tartrate-, mucate- and citrate-positive. Its antigenic structure is $VI_1.VIII$; $\longleftrightarrow e,n\ldots$(phase 2 is still under examination).

We suggest the name *S. bonariensis* for this new type.

Structure of the Branchiæ of *Carcinus maenas*

NOTHING is known concerning the histology of the branchiæ of *Carcinus mænas*, except for a brief account using Bouin-fixed material[1]. By fixation in Champy, whole-mount preparations of strips of a lamella stained in iron alum hæmatoxylin show that a system of branching tube-like structures is present.

The exact morphology of these structures is difficult to determine, but it is believed that they are tubes or sculpturings in the cuticle. Seen from above (*P*, Fig. 1) they form a series of connected systems extending radially out from certain areas, corresponding in position with the large pillar cells (*E*), which lie directly beneath.

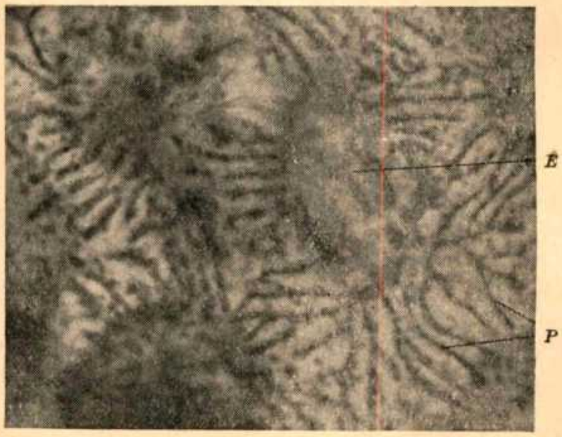

Fig. 1.

In transverse section of the lamella, shown diagrammatically in Fig. 2, the structures are seen as a series of dark striations (P') in the cuticle (C). Directly below these a number of tubes (T) extend deeply into the pillar cells, apparently forming a continuous arrangement with those of the cuticle.

There is no evidence available as to the possible function of these structures; but it is suggested that they form a tubular system whereby the water is enabled to come into close contact with the pillar cells, and thus assist in the oxygenation of the blood circulating between these cells.

Committee Decisions and Mathematical Statistics

Dr. Blakeslee is surprised that there is not a higher degree of unanimity of the Supreme Court of the United States[1], but a believer in the subjectivity of opinion would expect very much what Dr. Blakeslee records in the tantalizingly few data he gives. In some matters there can scarcely be two opinions. But the ordinary matters of government are commonly settled by committee decisions—of which those of the Supreme Court are a type—or else by the decision of some one man. If the values of the opinions of men *inter pares* are equal, one would premise first, that a wrong decision is equally as likely to emerge as a right one from subjective processes; and secondly, in relation to complex and obscure questions such as those with which superior courts necessarily deal, that the voting would correspond to some distribution of mathematical probability. Some critiques of examination results ("examinations of examiners") support these views[2]. It would be interesting to know how often a decision of a lower court of law is reversed or upheld by a higher.

Referring solely to a committee of nine members, all of whom vote, I may point out that if decisions were absolutely random the distribution of judgments in which the members were unanimous, or divided 8–1, 7–2, 6–3 and 5–4, would follow the binomial distribution ($n = 9$) 1, 9, 36, 84, 126. Thus a unanimous decision could be expected only once in 256 cases, and an 8–1 or a unanimous decision once in 25. The 6–3 and 5–4 decisions would constitute more than three-quarters ($\frac{210}{256}$) of all the decisions, and a decision of a higher degree of unanimity than 6–3 would occur only once in five or six cases.

Though the data supplied by Dr. Blakeslee are too few to have more than coincidental value, it is interesting to note that the two 6–3 and three 5–4 decisions he mentions are precisely in the ratio indicated by the binomial hypothesis. May I hope that someone with access to recorded decisions of the Supreme and other courts would examine them from the point of view of this hypothesis?

I am not concerned to question the value of Supreme Court decisions in particular, and I mention that Court only because there is evidently a body of its recorded opinions and of votings such as exists for few other committees. But if the subjectivity of committee judgments can be established, we may advance some way towards putting democracy on a factual basis. Much scorn has been poured on Hitler's "intuition", but it is not clear that the Allies have used any sounder method of attacking many of their problems. Yet the United States and the British Empire have virtually sole command of mathematical statistics, which is the only objective method of analysis of complex problems and offers the only way of assessing the validity of an analysis. Mathematical statistics is presumably not applicable to legal questions, nor to essentially subjective matters such as foreign policy; but it is applicable to many problems involving numerical data—such as those of supply, production and distribution. While the Allies continue to rely upon the decisions of committees or 'strong men' for problems capable of being objectively solved, they are disregarding the greatest intellectual advantage which they enjoy over their enemies.

Physiology of the Amino Acids

The valuable and comprehensive review by Dr. van Slyke[1] fails to discuss one problem, the most important of all from the point of view of human nutrition. Accepting W. C. Rose's classification of amino acids into essential and non-essential, he has omitted to make clear, though it is implicit in his review, that this information applies only to experimental animals, indeed, only to the experimental rat. It would be interesting to know what evidence, direct or indirect, exists, if any exists, as to the indispensability or dispensability of any individual amino acid for *Homo sapiens*.

RESEARCH ITEMS

Biological Estimation of Vitamin P Activity

A. L. Bacharach and M. E. Coates discussed this subject at a meeting of the Society of Public Analysts and Other Analytical Chemists held on April 1. Modifications of Zecho's method for measuring capillary resistance in guinea pigs having revealed its suitability as a basis for biological estimation of vitamin P, a provisional laboratory standard has been assigned the value of 1,000 units per gram: this material (W.S.P.1) is a water-soluble concentrate, similar to Szent-Györgyi's 'citrin', made from citrus peel. Recrystallized hesperidin has been found to have an activity of 95 units (probable limits of error, for $P = 0{\cdot}95$, 73–138 per cent), while a water-soluble concentrate made from blackcurrants has the high value of 10,600 units per gm. (probable limits of error, 79–126 per cent). Tests of this degree of accuracy are conducted on thirty to forty young guinea pigs, using two doses of standard and two doses of unknown. Rough exploratory tests, using six animals, have confirmed the presence of vitamin P in other citrus concentrates, in a reaction mixture obtained by partial esterification of highly purified hesperidin, in rose-hips and rose-hip syrup, in blackcurrant juice (pasteurized) and in blackcurrant *purée*.

A Modified Hilger Vitameter A

AT the meeting of the Society of Public Analysts and Other Analytical Chemists held on April 1, R. J. Taylor described a modified instrument for estimating vitamin A. Greater accuracy of calibration is attained by using, instead of a standard glass test piece, a dilute solution of a dyestuff, benzene-azo-*p*-cresol. This has an absorption curve resembling that of vitamin A with a maximum at 325 mμ; its E (1 per cent, 1 cm.) value can be determined accurately by means of a spectrophotometer, and its use automatically eliminates any small error in cell thickness. The modifications made in the instrument itself are: (*a*) a more versatile electrode holder, which reduces fluctuations of the copper arc, (*b*) a light-tight photographic paper holder, and (*c*) a pendulum type photographic shutter, giving a succession of short exposures instead of a single longer exposure at any one setting. After approximate visual setting, records are taken on a piece of gas-light paper at a series of neighbouring settings, from which the correct setting is ascertained. The instrument need not be operated in a darkened enclosure. The overall error has been reduced from about ± 10 per cent to about ± 3 per cent.

Constitution of Yeast Mannan

YEAST mannan, which is a polysaccharide extracted by alkali from baker's yeast, was shown by W. N. Haworth, Hirst and Isherwood in 1937 to be essentially homogeneous and composed exclusively of mannose residues, and its acetate and methylated derivative were studied. A further examination of the substance has been made by W. N. Haworth, R. L. Heath and S. Peat (*J. Chem. Soc.*, 833; 1941). It is shown that tetramethyl mannose, trimethyl mannose and dimethyl mannose are produced on methylation and that the tetra-fraction consists of tetramethylmannose and the di-fraction of 3 : 4-dimethyl mannose. The tri-fraction, however, is not constituted entirely of 2 : 3 : 4-trimethyl mannose; this sugar, in fact, does not make up more than 10 per cent of the tri-fraction. The main constituents are 3 : 4 : 6-trimethyl mannose and 2 : 4 : 6-trimethyl mannose, which are present in equimolecular proportion and together constitute 90 per cent of the fraction. This result throws light on the probable structure of yeast mannan, which is considered in the paper. The repeating unit of yeast mannan would appear to be composed of six mannose residues linked in such a way that two residues give rise to tetramethyl mannose, two yield 3 : 4-dimethyl mannose, one gives 3 : 4 : 6-trimethyl mannose, and one forms 2 : 4 : 6-trimethyl mannose. Alternative formulæ are discussed.

Geology of the Weald

THE geology of the Weald was formerly much studied, but then largely dropped as exhausted of interest. In the last few years, however, a good many valuable contributions have appeared, and a recent paper by P. Allen, "A Wealden Soil Bed with *Equisetites lyelli* (Mantell)" (Weald Research Committee, Pub. No. 31), is one of the fruits of the more intensive modern studies (*Proc. Geol. Assoc.* **52**, 362; 1941). One of its main findings is that fossil soil beds containing the underground parts of a large reed-like plant, *Equisetites lyelli*, in position of growth are widespread, thus proving the existence of terrestrial even if swampy conditions; and there are indications that these conditions occurred repeatedly. The underground organs of *E. lyelli* had been previously described, but their nature was not fully realized, and the species was ill characterized although it had been reported from the lowest Cretaceous rocks of various European and American localities. The present description of the rather thick elongated rhizome and the unbranched aerial stems makes this one of the best-known species of its genus.

A High-Voltage H.R.C. Cartridge Fuse

IN a paper read on April 15 in London before the Institution of Electrical Engineers, K. Dannenberg and W. J. John describe the construction of the two-element, powder-filled cartridge fuse and its effect on protection technique. The provision made for adapting the fuse for oil-immersion, and the striker-pin mechanism which ensures tripping on all three phases should only one fuse be blown, are described in detail. Discrimination in operation between fuses and other protective gear is discussed. Experiments are mentioned which show the ability of powder to prevent corona formation on the fusible conductor. A reduction in the magnitude of the transient voltages produced on fuse operation can be obtained by changing the section of the fusible conductor in one or more places. A series of tests on the behaviour of high-voltage fuses on short-circuit in an ordinary 50-c./s. system is presented and typical oscillograms are given. A test is also described which reproduces the operating conditions obtained when a rectifier backfires, and oscillograms are given showing the behaviour of the fuse under such a test. Fuses like those described have been developed for a rupturing capacity up to 1,000 Mva. at 66 kv. It is suggested that h.r.c. fuses can be used to improve fuse-switches, to act as a back-up to safeguard old circuit-breakers in cases where the short-circuit burden has been increased, and in combination with a simple load-breaking switch in which the switch deals with small overloads only, all short-circuits and heavy overloads being cleared by the fuse.

STALIN PRIZES FOR SCIENTIFIC STUDIES

IT is announced by the Tass Agency that the following awards of Stalin Prizes for outstanding scientific work in 1941 have been made by the Council of People's Commissars of the U.S.S.R.

Physics and Mathematics

First prizes (200,000 roubles each) to:

Serguey Bernstein, member of the Academy of Sciences of the U.S.S.R., for studies in mathematics "On Sums of Dependent Quantities with Mutual Regression Approaching Zero", "On the Approximation of Continuous Functions by Linear Differential Operator of a Multimolal", and "On Fisher's Probabilities".

Abram Joffe, member of the Academy of Sciences of the U.S.S.R., director of the Leningrad Institute of Physics and Technology, for studies in semiconductors published in his work "Semiconductors in Physics and Technology".

Leonid Mandelstam and Nikolai Papaleksi, members of the Academy of Sciences of the U.S.S.R., for studies on the theory of the oscillation and spread of radio waves.

Second prizes (100,000 roubles each) to:

Alexander Alexandrov, of the State University of Leningrad, for studies on the "Existence of a Convex Polyhedron and Convex Surface with Given Metrics" and "The Internal Geometry of Convex Surfaces".

Vladimir Kuznetsov and Maria Bolshanina, of the Kuibyshev State University in Tomsk for a study of "The Physics of the Solid Body".

Technical Sciences

First prizes (200,000 roubles each) to:

Boris Kalerkin, member of the Academy of Sciences of the U.S.S.R., for his studies in the theory of elastic equilibrium of cylindrical casings, together with the work on "Tensions and Changes in Circular Cylindrical Piping".

Sergei Khristianovich, corresponding member of the Academy of Sciences of the U.S.S.R., of the Central Zhukovsky Aero-hydrodynamic Institute, for a study on "The Flow of Gas around a Body at High Sub-sonic Speeds", "The Efficacy of Compressibility on Characteristics on Wing Contour", "Super-sound Flows of Gas".

Second prizes (100,000 roubles each) to:

Metislav Keldysh and Eugenii Grossman, of the Central Zhukovsky Aero-hydrodynamic Institute, for studies in the prevention of breakdown of planes, "Calculation of Flutter in Aeroplanes", "Oscillation of a Wing with Elastically Attached Engine" and others.

Chemical Science

First prize (200,000 roubles) to:

Nikolai Zelinsky, member of the Academy of Sciences of the U.S.S.R., for outstanding contributions to organic chemistry.

Second prizes (100,000 roubles each) to:

Ilya Grebenshchikov, member of the Academy of ciences of the U.S.S.R., director of the State Optical Institute, for studies in optics of great significance or defence.

Peter Rebinder, corresponding member of the cademy of Sciences of the U.S.S.R., for his studies The Importance of Physical and Chemical Processes n the Mechanical Destruction and Treatment of Solid Substances in Technology" and "The Acceleration of Deformation of Metallic Single Crystals under the Influence of Absorption of Superficially Active Substances".

Geological and Geographical Sciences

First prizes (200,000 roubles each) to:

Alexander Fersman, member of the Academy of Sciences of the U.S.S.R., director of the Institute of Geology, for his study "Useful Minerals of the Kola Peninsula".

Akhad Yakubov, vice-chairman of the Azerbaidjan Branch of the Academy of Sciences of the U.S.S.R., for the study "Mud Volcanoes of the Western Part of the Apsheron Peninsula and their Connexion with Oil Bearing".

Second prizes (100,000 roubles each) to:

Kanysh Satpayev, vice-chairman of the Presidium of Sciences of the U.S.S.R., for the study "Ore Deposits in Dzhezkazghan District of the Kazakh Republic".

Vasilii Shuleikin, corresponding member of the Academy of Sciences of the U.S.S.R., director of the Black Sea Hydrotechnical Station, for a study "Physics of the Sea".

Biological Sciences

First prize (200,000 roubles) to:

Yakov Parnos, of the Institute of Biochemistry of the Academy of Sciences of the U.S.S.R., for research in metabolism in muscles published in the work "Glycogenolysis".

Second prizes (100,000 roubles each) to:

Alexei Zavarzin, of the All-Union Institute of Experimental Medicine, for the study on the "Evolutionary Histology of the Nervous System".

Sergei Ognev, of the State University of Moscow, for the study on "Animals of the U.S.S.R. and Neighbouring Countries".

Economic Science

First prize (200,000 roubles) to:

Vladimir Komarov, president of the Academy of Sciences of the U.S.S.R., jointly with the following members of the Academy of Sciences: Ivan Bardin, Ergard Britske, Vladimir Obraztsov, Stanislav Strumlin, Lev Shevyakov, and Profs. Veniamin Veits, Nikolai Kolossovsku, Vassilii Kozlov, Boris Kuznetsov, Roman Pevzner, Abram Probst, David Chizhikov, and the scientific workers, Vladimir Galperin, Mikhail Rastsvetayev, Vyacheskav Rikman, Boris Gurevich, Ivan Doroshev, Mikhail Stekolnikov, for their joint work on the "Economic Development of the Urals in War Conditions".

Agricultural Sciences

First prizes (200,000 roubles each) to:

Johann Eichfeld, member of the Lenin All-Union Academy of Agricultural Sciences, director of the All-Union Institute for the Cultivation of Plants, for well-known works on the "Theory and Practice of Agriculture in the Extreme North of the U.S.S.R.".

Second prizes (100,000 roubles each) to:

Mikhail Dyakov, director of the Pushkin Zoo-Technical Laboratory, for works on the feeding of agricultural cattle and the elaboration of the foundations of the combined fodder industry.

Leonid Prassolov, member of the Academy of Sciences of the U.S.S.R., director of the Dokuchaev Soil Institute, for compilation of soil maps of the European part of the U.S.S.R. and elaboration of methods of calculation of land resources.

Medicine

First prizes (200,000 roubles each) to:

Alexei Abrikosok and Nikolai Anichkov, members of the Academy of Sciences of the U.S.S.R., for their studies on "Pathological Anatomy: Heart and Vessels".

Sergei Spasdkukopsk, of the Second Moscow Institute of Medicine, for well-known work in surgery and for the study "Actinomycosis of the Lungs".

Second prizes (100,000 roubles each) to:

Kolay Petrov, corresponding member of the Academy of Sciences of the U.S.S.R., for studies in oncology and the surgery of ulcers of the stomach and duodenum.

Sergeii Udin, chief surgeon of Sklifassovsky Institute, for his works "Notes on Field Surgery and Artificial Œsophagus", "Notes on Field Surgery", "Treatment of War Wounds with Sulphamide Preparations" and "Some Impressions and Reflections about Eighty Cases of Artificial Œsophagus".

Military Science

First prize (200,000 roubles) to:

Ivan Grave, of the Dzerzhinsky Artillery Academy, for the study "Ballistics of a Semiclosed Space".

Second prizes (100,000 roubles each) to:

Evgenii Barsukov, for the historical study "Russian Artillery in the World War".

Mikhail Dubinin, of the Voroshilov Academy of Chemical Defence of the Red Army, for studies in chemical defence.

History and Philosophy

First prize (200,000 roubles) to:

Vladimir Potemkin, Evgenii Tarle, member of the Academy of Sciences of the U.S.S.R., Vladimir Khvostov, jointly with a number of others for a work entitled "The History of Diplomacy".

Second prize (100,000 roubles) to:

Sergei Rubinstein, of Herzen Pedagodical Institute in Leningrad, for his book entitled "Foundations of General Psychology".

COSMICAL ORIGINS OF THE ELEMENTS

PROF. SUBRAHMANYAN CHANDRASEKHAR, assistant professor of theoretical astrophysics at the University of Chicago, described some results of his investigations of the origin and distribution of the chemical elements of the universe in a paper read during the fiftieth anniversary celebrations of the University of Chicago.

The formation of the lighter elements, including hydrogen and helium, can be accounted for at densities and temperatures not markedly greater than those found at present in the universe, but to account for the formation of heavier elements, such as oxygen, fluorine, neon, sodium, magnesium, aluminium, silicon, phosphorus, sulphur, chlorine, argon, potassium and their isotopes, in their present relative abundance, more extreme conditions are necessary. For the formation of the quantities of these elements in anything like their present relative proportions, the density of a 'pre-stellar' universe of one thousand to one hundred thousand grams per cubic centimetre and temperatures of $6–8 \times 10^9$ degrees seem to be required.

Under such conditions, however, the very heavy elements, like gold and lead, occur only in very small amounts; it thus appears that the pre-stellar stage must have originated at extreme densities and temperatures when the heaviest elements were formed. As the matter cooled to lower densities, the present relative abundances of the moderately heavy elements like silicon and sulphur resulted under conditions of a few thousand million degrees and densities ranging from one thousand to ten thousand grams per cubic centimetre. Finally, the elements lighter than oxygen were formed at a still later stage, when conditions were not very different from those now existing in stellar interiors.

In discussing the formation of energy in giant stars, Prof. Chandrasekhar stated that whereas the Bethe theory successfully accounts for energy production in the sun and similar stars, it fails to explain energy production in the giants. His own calculations show that the production of energy by the lighter elements, including lithium, beryllium and boron, will take place in a spherical shell rather than close to the centre—burning, so to speak, from the centre outward. The energy-generating spherical shell cannot get very far from the centre, leaving only the inner 35 per cent of the star's mass to provide energy; this, he believes, accounts for the presence of the light elements in the atmospheres of the giants.

The theory that supernovæ constitute an intermediate stage in which extremely heavy stars cast off much of their mass in their 'attempt to settle down as white dwarf stars' was put forward by Prof. Chandrasekhar. He pointed to the analysis by Dr. Minkowski, of the Mt. Wilson observatory, of the central star of the Crab nebula, which was identified as the result of a supernova in our galaxy, which 'blew up' in A.D. 1054. His analysis of Dr. Minkowski's results showed that this nuclear star is half-way between the supernova and the white dwarf stage: thus, it will be a white dwarf by approximately the year 2828.

According to the theory of white dwarfs developed by Prof. Chandrasekhar, the upper limit to the masses of white dwarfs is about twice the mass of the sun. Thus, he said, a massive star may undergo great contraction, bringing about the explosion characterizing the supernova.

RECENT RESEARCH IN OCEANOGRAPHY*

By DR. G. E. R. DEACON

THE papers in the most recent number of th *Journal of Marine Research* of the Bingham Oceanographic Laboratory, Yale University, for 194 cover a wide field.

R. B. Montgomery has used four series of observations across the Straits of Florida near Habana t compare the calculated difference of sea-level between the two sides of the Gulf Stream with th figure given by the tide-gauge readings at Key Wes The agreement was poor, and among the mai sources of error new emphasis is given to the di tortion of the picture of the density distributio which is inevitable owing to the change of tide the ship works her way across the strait—taking about sixteen hours to complete the section. Better agreement between calculations and tidal data has been obtained farther north along the U.S. coast, and it is suggested that the exposure of the tide-gauge at Key West is not altogether satisfactory.

---

* Sears Foundation for Marine Research. Bingham Oceanograph Laboratory, Yale University. *Journal of Marine Research*, 4, No (1941).

G. L. Clarke has measured the water transparency and light penetration over a large area south of Bermuda as far as the coast of British Guiana. The waters of the Sargasso Sea and North Equatorial Current were clearest; there was less transparency in the more fertile waters nearer the equator and a sharp drop near the South American coast. The measurements were made with photo-electric cells and compared with observations of the depth to which a 'Secchi disk'—a white disk 20 cm. in diameter—could be lowered before it disappeared. The correlation showed a high degree of scatter, but on an average the disk disappeared at a depth where the illumination was 15 per cent of that incident on the surface. The greatest depth to which the disk was seen was 47 m.; the poor agreement with direct measurements is believed to have been due to unfavourable weather conditions and large waves; the disk was viewed directly over the ship's side and not through a tube dipped below the surface.

H. W. Graham has examined the plankton hauls made from the non-magnetic ship *Carnegie* on her last, ill-fated voyage from California to Samoa. The hauls, which were made from a depth of 100 or 150 m., showed a richer plankton in the tropical region, where there is evidence of the upwelling of deep water, than in the southern part of the temperate zone, where there is an accumulation of warm water with less nutrient salts. The author does not mention recent work by Seiwell and Riley, which has an important bearing on the subject.

F. A. Davidson and Elizabeth Vaughan, of the newly constituted United States Fish and Wildlife Service, describe their work on the relations between density of population, size of fish and time of spawning migration for the pink salmon of south-eastern Alaska. Between 1914 and 1920 while the fishery was expanding rapidly the fish declined in abundance, but increased in size and migrated to the rivers at an earlier date. After 1921, when restrictive regulations were introduced, the fish began to regain its former abundance, but decreased in size and migrated later. The authors summarize many influences which have been found to retard growth in a crowded population, such as the production of autotoxins, rowth-inhibiting substances, accumulation of excre-ory products, reduction of available food, and over-stimulation due to increased contacts, but they are nclined to believe that the changes in the pink salmon re mainly the result of the varying competition for ood as the population increases or decreases.

Mary Sears compares the phytoplankton productivity of the shallow water over the Georges Bank n the Gulf of Maine with that of the neighbouring deeper waters. It was found that the period of diatom abundance lasted longer in the shallow water; the deeper waters are as rich or richer during the peak eriod at the end of March, but become relatively arren at the end of a month, while the population f the shallow water falls to a twentieth of its peak alue at the end of three months. The bank was thus found to be one of the most productive areas f the gulf.

C. E. ZoBell has combined the most desirable eatures of many bacteriological water-samplers to produce one which he claims to be non-bactericidal, easily sterilized and capable of aseptic manipulation under the usual collecting conditions. No metal was satisfactory and the containers were made of glass or indiarubber, sealed with a 4-mm. capillary tube attached by pressure tubing. The frame which holds the container is so arranged that the capillary is broken at a file-mark by sliding a 'messenger' down the wire on which the sampler is lowered. The indiarubber containers were used at the greater depths to avoid the effect of the sudden change of pressure on the bacteria when the sample was aspirated through the broken capillary; the containers were sealed hot and full of vapour, straight from the autoclave, and the indiarubber bulb was sent down in a collapsed state, to aspirate a sample as it returned to its normal shape. The possibility of exchange through the capillary while the sampler was being hauled to the surface was not thought to be serious: owing to the continuous reduction of pressure the main movement is outward.

SMOKE ABATEMENT AND RECONSTRUCTION

Many minds are turned to post-war conditions, when problems such as unemployment will coincide with opportunities for reform of layout and rebuilding of cities. The National Smoke Abatement Society has submitted to the Ministers concerned a memorandum on smoke prevention in relation to initial post-war reconstruction in Great Britain (Nottingham: National Smoke Abatement Society, *2d.*).

The memorandum is concerned only with the prevention of smoke in the new building that will take place immediately after the end of the War. Provided that early attention is given to this question, it is considered that practically the whole of this building can be made smokeless.

The memorandum first proposes that the important principle be established of ensuring the use of suitable appliances and plant by requiring all new installations of fuel-burning equipment to have the previous approval of a special authority. By this method, which is common in the United States and elsewhere, both fuel economy and smoke prevention can be promoted.

The complete smokelessness, it is said of commercial buildings, that is, all premises other than industrial and domestic, may be readily achieved and should certainly be assured. Open fires should not be permitted in such premises except in special cases, when the use of smokeless fuels should be made obligatory. Industrial plant of all kinds is included in the proposals for the previous approval of new installations, and in many cases the control should also cover use and maintenance.

Much can be done to improve the standards of heating in domestic houses and flats apart from smoke prevention, but if the requisite attention is given to the problem in good time, it is likely that either the whole or a great part of the new housing could be made completely smokeless. The chief problem appears to be that of the supply of smokeless fuels suitable for open grates and other appliances, which must be correlated with the volume and rate of housing. This and other questions should be examined by a Government committee or board, which should include representatives of Government departments, fuel and appliance industries, and town planning, housing, and smoke abatement authorities.

Smokeless central areas should be established in all large towns. Not only should new premises in such areas be smokeless, but also powers should be given to enforce the smokelessness of existing premises. In this way the whole of the most important area of a town could be made completely smokeless.

Town planning schemes in general should include additional measures for ensuring smoke prevention, especially in relation to the zoning of industry and the establishment of special industrial areas or estates. The possibilities of district heating for all types of area should be fully examined and this method adopted wherever it is found to be advantageous. Committees, national, regional and local, concerned with post-war planning, should be assisted in their work by existing regional smoke abatement committees or others experienced in smoke prevention matters.

Support is given to the proposals that have been made in many quarters for the formulation of a comprehensive national fuel policy and for the establishment of a Ministry of Fuel.

It is a commonplace that post-war reconstruction offers great opportunities. So it was thought after the War of 1914–18, when a departmental committee of the Ministry of Health reported on the same question and commented that "the chief factor in the failure to deal with the smoke evil has been the inaction of the central authority"—to which might be added the local authorities. As the memorandum shows, this is a case where technical knowledge is in front of public and official opinion.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public)

Monday, April 27

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5 p.m.—Mrs. Stephen Courtauld: "In the Netherlands Indies" (Kodachrome Films).

Wednesday, April 29

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. R. Fitzmaurice: "The Post-War Home", 10: "Lighting, Heating and Ventilation".

Thursday, April 30

Institute of Fuel (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 2.30 p.m.—Dr. S. G. Ward and Mr. W. J. Morison: "Practical Application of Gas Producers to Road Transport including Passenger Service Vehicles".

Royal Institution of Great Britain (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. E. J. Salisbury, F.R.S.: "The Weed Problem".*

Friday, May 1

Geologists' Association (in the Geological Society's Rooms, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. V. C. Illing: "Geology Applied to Petroleum".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Master (Graduate in Engineering with works experience) to be responsible for the teaching of Engineering in the Consett Secondary School and Technical Institute—The Director of Education, Shire Hall, Durham (May 2).

Principal of the Walker Technical College, Oakengates—The Secretary for Education, County Buildings, Shrewsbury (May 16).

Head of the Chemistry Department—The Secretary, Robert Gordon's Technical College, Aberdeen (May 30).

LEADERSHIP IN INTERNATIONAL RELATIONS*

IN "The Twenty Years' Crisis", Prof. E. H. Carr set out to make a contribution to the science of international relations, but somehow he seemed to lose his way in the maze of power politics. Without any such avowed purpose, he has now given us in "Conditions of Peace"* a constructive analysis in the true scientific tradition, which is a real contribution to the establishment of such a science. It is indeed more than a clear, dispassionate analysis of past ills and present problems; a foreshadowing of future needs ; its calm application of the scientific spirit to world affairs has something of great nobility and vision.

The combined insistence on realism and on learning the mistakes of the past, with the fearless scrutiny of the future, give the book special claims on the interest of scientific workers. Prof. Carr's whole approach is in harmony with the outlook which they are accustomed to bring to bear on their own problems, if not always on those which they face in common with their fellow-citizens. They will recognize instinctively the force of his warning of the danger to the future welfare and prestige of Great Britain of the common inclination to assume that once Nazism is defeated and Germany rendered helpless, the world can with relatively little trouble be re-settled on familiar and comfortable lines. The future, he urges, lies with those who can resolutely turn their back on the old world and face the new world with understanding, courage and imagination.

This call to leadership, which is the dominant note of the whole book, is the complete answer to the vague charges of obscurantism which have found utterance from some of those quarters still looking to the past, as it refutes those who would attempt to maintain the departmentalism or sectionalism of life which has been responsible for so much frustration in the past generation. If democracy is to recover its vitality, to meet the challenge of this present revolution by a redefinition and re-interpretation, science must make its own contribution. The conditions for an orderly and progressive development of human society cannot be worked out without the help both of scientific method and of scientific investigation. Once we begin, as Prof. Carr points out, to put first things first, to determine the conditions for mankind's continuous advance, many of the obstacles to scientific and political co-operation will disappear. When we cease to make peace and security the objects of policy, and policy and plans are formulated to serve clearly ascertained general needs and not private or sectional interests, it will be possible for scientific men to make their contribution to the solution of the economic, social and technical problems involved without detriment to their primary allegiance to science.

That contribution would be the more easily made if scientific workers encountered more often the scientific temper and outlook which characterize Prof. Carr's admirable book. He brings to his survey exactly the quality for which General Smuts pleaded in 1929 in his Sidgwick Memorial Lecture on "Democracy", and there are few scientific workers who will not readily respond to this challenge to thought. He does not attempt to cover the whole field of the future settlement and eschews anything of a blue-print for a peace treaty. He ignores the Far East, and dismisses the United States, the Colonial problem and Russia somewhat cursorily, but within his limits he probes for fundamental principles and the real causes in a way that should inspire equally constructive and imaginative thinking about the problems which he has left alone.

---

* Conditions of Peace. By Prof. Edward Hallett Carr. Pp. xxiv + 279. (London : Macmillan and Co., Ltd., 1942.) 12*s*. 6*d*. net.

With its insistence on the factor of leadership, the book is characterized by a breadth and sanity of outlook which sees the whole problem and not merely one section of it, that are badly needed in many circles occupied with reconstruction plans to-day. The relation between domestic policy and foreign policy, the importance of facing reconstruction now and not merely after the War are clearly seen, and a chapter on "Britain at Home" forms as homogeneous a part of the book as those chapters in which he analyses so acutely the theory of self-determination and outlines the new Europe which might be our objective.

In examining the problems of peace from the specific angle of British policy, we must recognize that Great Britain can play no dominant part in the ordering of the world after the War unless the people of Great Britain maintain in time of peace the same sense of common purpose and obligation which has been developed under the impulse of war. Moreover, it is equally inconceivable that we can play a leading part in the reconstruction of the world and leave the structure of society in Britain unchanged and unaffected. What we can achieve in Europe and in the world will grow out of, and is largely dependent on, what we can achieve at home.

In the chapter in which Prof. Carr is urging that we should turn to account in peace the lessons learnt in waging war, and project into post-war reconstruction the organizations or institutions established primarily to serve war purposes, he is once again calling for the forward-looking mind. The opportunities which the imperative need for radical re-planning afford must be seized, and we must recognize that the purpose of our economic system is to produce things wanted for consumption, not things which it is profitable to produce. The bearing of the social minimum not merely on the unemployment problem but also on industrial and agricultural policy and on international reconstruction and relations with the Dominions, the United States and with post-war Europe are outlined tersely but lucidly, and the chapter includes an outline of agricultural policy embodying principles for which scientific workers have long been contending. The emphasis placed on research, like the acute analysis of the weaknesses of party politics in this same chapter, are other points for which scientific workers may well be grateful, and they cannot fail to respond to its challenge to the constructive thought and determined action required to effect the changes essential in our democratic institutions, if democracy is to remain a reality in the twentieth century.

Prof. Carr's insistence on the moral challenge is in striking contrast with the somewhat materialistic note he struck in "The Twenty Years' Crisis". In his glance at democracy he emphasizes the necessity for developing a sense, not only of common benefits to be derived from the State, but also of common obligations, and particularly that of a common responsibility to make democracy work. The democratic ideals of equality and liberty must be reinterpreted in predominantly economic terms, and the new democracy must win the struggle to make political rights effective over economic power. In regard to economic reconstruction, he suggests that the first essential is to draw up an infinitely expansible plan of consumption, with graded priorities, which will assure that our productive forces are occupied to their fullest capacity for its fulfilment, and secondly to substitute welfare for wealth as our governing purpose.

The core of the book lies in the chapter on the moral crisis, in which Prof. Carr outlines the faith and spirit in which the problem of the new Europe and the new order must be approached. The emphasis must lie on positive achievement of good rather than the negative avoidance or suppression of evil. The appeal must be essentially to the individual, to the 'little man', in order to restore his sense of being a constituent member of the community. It must address itself first to the solution of the economic problem, without necessarily expressing itself in economic terms. It must approach the unemployment problem by creating needs vast enough to make a full call on our resources and imperative enough in the moral sphere to command the necessary measures of sacrifice to supply them. The new faith must solve the unemployment problem by providing a moral purpose as potent as was religion in the Middle Ages, or as is war to-day. Its emphasis must be more on obligations than on rights, on services to be rendered to the community rather than on benefits to be drawn from it, and must provide for a similar adjustment in the international field, where a new synthesis of liberty and authority must be achieved.

It is in this spirit that Prof. Carr urges that the immediate post-war activity of the victors should be centred on the economic and social needs of the occupied areas, and that political and constitutional issues should be postponed to a later date. The urgent need is to alter, not the location, but the meaning of frontiers. He argues convincingly as to the impossibility of Great Britain escaping from her responsibilities in Europe, and insists on the imperative necessity of carrying forward unimpaired into the period of peace those forms of co-operation and control which have already been created. We must begin by creating the framework of an international order and then encourage national independence to develop and maintain itself within the limitations of that framework.

Prof. Carr's suggested solution of the German problem is a corollary of this policy of developing new loyalties by giving provisional arrangements an opportunity to demonstrate their value and indispensability. We must help to build up the German economic system into a larger unit under different forms of control, and overcome her belated nationalism by making internationalism worth her while. It is important to defeat Germany by overwhelming force; but it is also important to convince Germans at the earliest possible moment that we have other credentials than force for the reorganization of Europe. The German masses must be given from the outside reasonable convictions that the new order will bring them a higher measure of spiritual, social and physical well-being than the old. Positive incentives to Germans to keep the peace must be provided and opportunities to co-operate in maintaining it.

Without a cogent appeal to the youth of Europe for service to a larger cause there can be little hope of building a new order or solving the many vexed political and economic problems on which Prof. Carr touches with such insight and realism. Some may hold that he is too optimistic and dispassionate in his estimate of Germany, but as to the need for a new spirit, an unprejudiced mind and a sense of values there can be no question, and even those who may think him too cautious can scarcely fail to admit the accuracy of much of his diagnosis and the value of the suggestions he so tentatively advances.

Moreover, there is already evidence of a substantial volume of opinion in harmony with Prof. Carr's views. E. Müller-Sturmheim in his thoughtful article, "Germany as a Spiritual and World Problem" in the *Quarterly Review* of October last, outlined very similar conditions designed to make it impossible for the German people to re-establish their war machine, and at the same time to convince them that their real national and political unity are safeguarded without soldiers or armaments. Any permanent solution must free the German robot from the fear of encirclement inspired by his leaders, and at the same time free him from the unrestricted rule of a total militarism. When, as Müller-Sturmheim points out, the hearts and minds of the German people are thereby opened to the voices of those great Germans whom militarism has hitherto deprived of their influence, the firm integration of Germany into a new world order will be immensely facilitated.

Much the same idea that the new organization of Europe should be directed so as to divorce national structures from military and industrial power, and should be backed by a world control of raw materials and communications, with the dual object of faciliating economic expansion and thwarting policies of autarchy and militarism by automatic sanctions, is o be found in the P E P broadsheet, "The Future of Germany". This broadsheet visualizes the post-war settlement of Europe along the lines of the British Commonwealth, rather than with a written constitution. From this point of view even the disruption of Germany into its original large units existing before 1871, suggested by Dr. P. Einzig in his recent book*, is not necessarily contrary to the modern trend towards larger and more closely integrated units if the original German States are re-integrated, not into a German, but into a European unit.

Dr. Einzig's study of appeasement is scarcely less searching than Prof. Carr's analysis, but his treatment of the German problem is more drastic and far-reaching. Even those who regard his proposals as too provocative cannot disregard his sombre warning against the danger of economic appeasement and the dominance of purely financial interests. Dr. Einzig, it is true, may lay himself open to the charge of making security an object of policy, but it involves constructive measures designed to assist the non-Prussian German States to settle down to peaceful activities and abandon their world-conquering ambitions, and to work out a satisfactory existence. Moreover, he frankly recognizes what is often forgotten, as Prof. Carr reminds us, that no durable peace can be made unless those who have the power have also the will, in the last resort, after having tried all methods of persuasion, to take and enforce with vigour and impartiality the decisions which they think right.

Equally it is important that those who have the power should recognize the moral obligation which alone makes its exercise tolerable to others. This vital truth appears to be overlooked by Dr. Einzig in urging a declaration in favour of a hard peace. That may well have its place in the moral offensive which others besides Prof. Carr have stressed, notably Mr. J. F. Dulles in the American periodical *Fortune*. The importance of propaganda has been overlooked in our war effort, and Dr. Einzig is on sure ground in directing attention to the value of an emphatic assurance to the conquered peoples that after British victory they would not be left at Germany's mercy. That assurance need not be based on the motive of hate which Dr. Einzig inclines to suggest in his account of the mistakes of appeasement. It must be based on the quiet, dispassionate analysis which Prof. Carr gives us.

It is encouraging to find how much of this admirable analysis finds a counterpart in Mr. Dulles's stimulating article. Very clearly, thought in the United States is moving on similar lines, and opinion there is indeed more, rather than less, likely to support a hard peace than in Great Britain. The keenness of Mr. Dulles's analysis of the Atlantic Charter and his insistence on realistic thinking and on the need for a change in outlook and for real political education should be carefully noted. If the conditions of peace sketched out by Prof. Carr are to materialize, with all the implications they connote, scientific workers must make their own contribution. They have a part to play in the political education required and in carrying into the political field the spirit and method of science. The readiness to accept change and the forward-looking mind are part of their own tradition; the Anglo-American co-operation in science already being forged as part of our war effort may well be extended to lay the foundations of a true science of politics and of international relations, without which the evolution of world order must remain visionary. Even among the great democracies, politics was, and still is, too much at the mercy of prejudices and catch-phrases. War-time parliamentary elections in Great Britain have shown the dissatisfaction of electorates still approached in the old fashioned way. With the spread of adult education, and with the growth of understanding, of themselves and of each other, of the English-speaking peoples and active co-operation with the U.S.S.R. which war-time needs have made imperative, the development of political science on a world-wide basis has become a possibility which cannot fail to leave its mark on the history of civilization.

* Appeasement Before, During and After the War. By Paul Einzig. Pp. xii+216. (London: Macmillan and Co., Ltd., 1941.) 10*s.* 6*d.* net.

EDUCATION AND TRAINING OF ENGINEERS

FOR some time past the Government, industry and the teaching institutions have been working in common towards the creation of a body of skilled engineering personnel in Great Britain adequate to meet the enormous productive and operational needs of the war machine. Much of the system which has evolved, and is still evolving, will be unsuited to a long-term peace-time policy, but the contrast with pre-war procedure has emphasized the need for reconsideration of the whole plan of technical education and training. It is at once evident that the problems involved will not be solved by individual effort, however well conceived, of particular sections either of industry or educational authority. Each has a vital part to play, but it is essential that the separate efforts be linked together intimately in a national plan, and it is gratifying to observe that steps are already being taken in this direction.

The result of a preliminary consideration of the problem by the Education, Training and Personnel Sub-Committee set up some months ago by the Post-War Planning Committee of the Institution of Electrical Engineers was presented in the form of a paper read by its chairman, Dr. A. P. M. Fleming, before the Institution on March 19. The paper opens by emphasizing the need for a broader conception of the aims of technical education on the part of both the educational institutions and of industry, and by quoting the Adult Education Committee of the Ministry of Reconstruction of 1919 as follows:

"Technical education has only too often defeated its own object by the narrowness with which it has been conceived and carried out. . . . Technical efficiency is primarily dependent on qualities requiring for their growth opportunities for expression which cannot be adequately provided within the range of purely technical studies."

That this expression of opinion was no less appropriate in 1939 was due in large measure to the fact that industry, taken as a whole, had failed to accept adequate responsibility not only for the effective practical training of its employees but also for their part-time day release for technical instruction. Th latter made necessary a general adherence to th system of evening-class instruction, a system whic not only restricts unduly the scope of the technica instruction possible but also leaves no time for th fostering of cultural interests, and imposes consider able strain on the physical well-being of the students It is shown that on the average during the 1936–3 period no more than 10–20 per cent of the boys wh entered upon the first year of National Certificat courses in engineering remained to enter the fift and final year, and that few of those who withdrew transferred to alternative, more practical, courses Of no less serious import, however, is the fact tha the evening courses provided failed—and mus inevitably fail—to stimulate the inclination fo independent reading and thinking, and tend t stultify rather than encourage the processes o critical analysis. The effect of these restriction was evident enough during the pre-war period ; it ha since been more serious.

The general replacement of evening technica instruction, in whole or in part, by part-time day instruction, with the evening periods then left free under careful guidance, for independent technica study and for the fostering of cultural interests, mus be regarded as an essential item in post-war planning Then, and only then, will it be possible for th technical colleges of Great Britain to attain thei full status as centres of adult education in th broadest sense.

To this end it will be necessary for the colleges t give much increased attention to the education o the craftsman as distinct from the technician. Th former, generally speaking, reach their highest leve of responsibility at the age of twenty-one or less and the problem of ensuring a healthy attitude o mind towards their employment and an improved utilization of leisure hours is a very real one. It solution will demand not only an effective presenta tion of the vital importance of craftsmanship in th national life, but also the raising of the status o craft instruction in the colleges and the improvemen of personal amenities for craft employment. It i suggested that a national apprenticeship scheme b introduced, sponsored by the Ministry of Labour, a the co-ordinating body for industrial concerns, an the Board of Education, acting similarly for the loca education authorities. On the one hand, this woul require the provision throughout industry of organize courses of practical training, involving possibly th creation of special apprentice workshops and th use of the now well-established Ministry of Labou training centres ; and on the other, extended course of instruction in manual processes leading to suc aspects of workshop administration as fall within th responsibility of foremen, inspectors, rate fixers an the like.

The scope and difficulty of the whole problem o educating and training engineers, and indeed a technical personnel, has increased, and will continu to increase, with the rapid expansion of scientifi knowledge and technical development, and with th necessity which these impose of increased specializa tion for the technician and of change from craft to highly mechanized conditions of employment for the artisan. Too much stress cannot be laid on the need in all cases for ensuring an adequate foundation of general education to the appropriate level prior to specialization, and a full appreciation of the purpose of the significant specialized activity in relation to the life and welfare of industry and the community.

A special responsibility in this respect falls on the universities. It is suggested that there are two vitally important needs of industry in Great Britain which it should be the function of the universities to satisfy. One is for men capable of interpreting scientific progress in relation to industrial possibilities and of applying scientific methods of analysis to the problems which arise in each progressive stage of technical development. The other is for men who combine with adequate scientific and technical knowledge the personal qualities and power of leadership specially necessary on the productive and administrative sides of industrial organization. At the present time, the engineering schools tend to treat all students as though they are destined for high-grade scientific or technical work. Those who are—and indeed all—will be better for a broader scientific foundation, less specialization and fuller opportunity to take part in the corporate life of the university. Those who are not—and in an average year the proportion is high—should be permitted to replace the more advanced stages of the mathematical and technical work by studies in such subjects as the social sciences and economics.

To this educational preparation must then be added the practical and essentially technological parts of the training, and in neither respect are the present provisions satisfactory. Many large firms still make no provision for the systematic practical training of their graduate recruits, while those who do pay too little attention to the efficiency, or inefficiency, of the process by which the graduate acquires the information and experience to be gained. In keeping with Sir Richard Livingstone's views, it is suggested that all prospective university engineering students should be required to spend one year in industry between leaving school and entering the university. So long as reasonable continuance of scientific and mathematical study is ensured, and that satisfactory provisions are made within industry for the practical instruction of the boys concerned, this arrangement would be advantageous in every way. It would seem to offer the most effective means of self and guided selection, and the opportunity it would afford for mental adjustment is of the greatest importance.

At the post-graduate stage the continued practical training, leading, after the appropriate period, to the choice of, and concentration on, a particular branch of engineering work, requires to be supplemented in a much more effective manner than has been the case with systematic technological instruction. The amount of information and accumulated experience which a man must acquire before he can hope—or be expected—to make an original contribution to development is often so great that its acquisition purely by independent effort may be an extremely inefficient process. In recognition of this, a few firms have provided suitable lecture courses and afforded opportunities for discussion as an integral part of their training schemes. The disadvantage of this arrangement is that access is limited, and there is great need for supplementary provisions in the local colleges and universities similar to those instituted in the Manchester area in 1937 under the auspices of the regional advisory committee responsible for co-ordinating technical and other forms of further education. The circular announcing the first series of advanced lecture courses stated: "It is probable that there are many engineers engaged in the highly differentiated engineering industry of the region who would be attracted by courses of lectures dealing with specialized problems related to their daily work. If these lectures were given by specialists in intimate relation with the practical problems of industry, if they attracted engineers who, in their professional capacity, were directly concerned with the subject-matter of the courses, and if the lectures were informal and provocative of discussion, it is believed that they would constitute a useful innovation in engineering education in the region." This scheme offered no attractions in the form of certificates and afforded no artificial examination stimulus to the acquisition of knowledge. Its operation was temporarily discontinued in 1939, but the success and extension of this type of scheme is a matter of considerable educational interest and importance.

The report submitted by the Sub-Committee of the Institute of Electrical Engineers concluded with a discussion of the short-term problems of education and training which will arise in the immediate post-war period. The drafting into industry of men now with the Fighting Services and in Service establishments will present many difficulties; special provisions will have to be made in industry and the educational institutions to cater for the diversity of needs of both industry and the men concerned. Government grants will be required to cover the expenses of the training period. It is emphasized that these should not become the prerogative of ex-officers only, but should be available to all men with the necessary qualifications, experience and promise—a principle which has already been established in the recently instituted scheme of State bursaries. With the view of preparing the ground, the Committee intends to collect data concerning members of the Institution of Electrical Engineers now engaged with the Services and to make an assessment, so far as, and as soon as, is possible, of the probable personnel demands of the various branches of the electrical engineering industry and of the extent to which each firm can absorb, for purely training purposes, personnel outside its own requirements.

At a time of uncertainty like the present, little can perhaps be done in this direction, but it is beyond doubt that, having recognized past deficiencies, the whole of the engineering industry in Great Britain will support wholeheartedly any movement which has as its object the well-being and proficiency of its vast personnel.

CYTOPLASM OF THE PLANT CELL

The Cytoplasm of the Plant Cell

By Prof. Alexandre Guilliermond. Authorised translation from the unpublished French manuscript by Dr. Lenette Rogers Atkinson. (A new Series of Plant Science Books, Vol. 6.) Pp. x+247. (Waltham, Mass.: Chronica Botanica Co.; London: Williams Dawson and Sons, Ltd., 1941.) 4.75 dollars.

PROTOPLASM, the physical basis of life—to use Huxley's oft-quoted aphorism—is the very stuff of life, but its mystery lies not merely in its composition but even more in its organization. The correlation between the structure and behaviour of the nucleus and the demonstrable facts of heredity is one of the outstanding achievements of modern science. Possibly for this reason the study of the cytology of the cytoplasm has suffered in comparison with the cytology of the nucleus. Particular interest is attached, therefore, to this book by Prof. Alexandre Guilliermond, professor of botany in the Sorbonne.

Written by a pioneer investigator, the work is the most complete account in English of the contributions to our knowledge of the cytoplasmic inclusions which have been made by the French school of cytologists of which Prof. Guilliermond has been the leader. Translated from an unpublished manuscript in French, the book is vol. 6 of a new series of plant science text-books published by the Chronica Botanica Company and it contains a foreword by Prof. William Seifriz, who is also a notable contributor to knowledge of plant protoplasm.

The cytology of the cytoplasm and of the nucleus must be approached in different ways. These differences lie not only in the laboratory methods, though Prof. Guilliermond has much to say on this subject. The nuclear cytologist deals with what is usually the largest of the cellular inclusions and yet by his technique he often paints miniatures, although they are often exquisite in detail and definition. Though he may investigate the most minute living inclusions known in plant cells, the cytoplasmic cytologist must allow his attention and vision to roam over the entire range of a varied cytoplasmic 'landscape' and must portray—as in a swiftly executed water-colour—the ever-changing cytoplasmic scene. Understanding and appreciation of Prof. Guilliermond's eminently readable account will grow as the reader recognizes and accepts that the cytological problems of the cytoplasm have, of necessity, been approached by distinctive methods.

To the student of cell physiology the work is of the greatest interest. Much of physiology has been dominated by the desire to explain vital processes in terms of the accepted principles of physics and chemistry deduced from observations *in vitro*, and too often too little attention is paid to the milieu in which they occur *in vivo*. Plastids and vacuoles are two of the inclusions of great interest to the student of metabolism concerning which cytology has hitherto had but little to say. Plastids as living inclusions in the cytoplasm are intimately concerned with carbohydrate metabolism; vacuoles are usually recognized as liquid inclusions in the cytoplasm, characteristically able to accumulate salts and solutes and are regulated in this behaviour by the vital processes of the cells. Full understanding of photosynthesis and of mineral nutrition awaits a complete knowledge of the part which these inclusions play: Prof. Guilliermond's account of their morphology and development is a contribution to this end.

It is inappropriate to anticipate the conclusions which only emerge as one follows Prof. Guilliermond in his skilful path through the maze of mitochondria, chondriosomes, chondrioconcts, plastids and the thread-like, colloidal progenitors of vacuoles. In Prof. Guilliermond's view the chondriome of green plants consists of two types of inclusion which are not always distinguishable on morphological grounds but which, nevertheless, preserve their identity throughout the development of the cells. Of these, one type is characterized by its greater ability to elaborate carbohydrates and develops into plastids, whereas the other type remains minute and its members are regarded provisionally as "inactive chondriosomes". Plastids only have the "chondriosomal form" in their inactive phases and it now appears that their subsequent change in form may be reversible. Prof. Guilliermond takes frequent occasion to remark, with apparent justification, that one must be suspicious of analogies in shape for inclusions as different, as young vacuoles and the thread- or rod-like chondrioconcts may, at certain stages, be similar: in such cases the evidence of chemical composition or of development is marshalled to determine their identity.

A multiplicity of terms may be inevitable in so descriptive a subject but some may feel that this has gone to excess. "Gliode" to denote a colloidal system only to be found in living cells is a case in point. Furthermore, some well-established terms are not used in their precise technical sense. For example, 'crystalloid' is used as though synonymous with 'crystal' and the terminology used to describe colloidal systems seems unnecessarily involved and unfamiliar. The terminology of fats and fatty substances of complex composition has for long been a frequent source of confusion. Many would no doubt prefer 'lipoid' to 'lipide' to denote substances with the solubility and other general properties of fats, while "gluceride", on p. 26, seems an obvious misprint for 'glyceride'. Lecithin-like substances for which the term lipines is often used are somewhat elaborately termed 'phosphoaminolipides', and their identification as the chief components of minute inclusions in the cell is described: this identification, based on microchemical tests alone, may appear too sanguine to the critical biochemist.

For the most part the style is admirably concise and vivid—especially in the morphological descriptions. However, even brevity may be carried to extremes and some of the descriptions of the physico-chemical characteristics of cells are for this reason meaningless: this is the case in the following passages: "The ratio cholesterol : fatty acid, or the lipocytic coefficient, is characteristic of a given species. It constitutes a cellular constant. There also exists a mineral constant. Similarly the water content for each type of tissue always fluctuates about the same value, therefore each type of tissue in a species possesses a constant and specific content of water of imbibition. Water is thus a cellular constant." Nevertheless, physiologists should not be deterred by this cursory treatment of these aspects of cell physiology from reading the rest of the book.

A historical point arises in connexion with the vacuole. De Vries is credited with the discovery of plasmolysis. Most authorities credit de Vries with the first use of the term, but the first observation of the process is usually attributed to Nägeli in 1855.

Prof. Guilliermond's book was published in 1941. English readers will be gratified that this new account of so much French cytological work could be published in the United States despite the collapse of France. The preface states that Dr. J. Dufrenoy, who is well known to many English and American botanists and who was at one time an associate of Prof. Guilliermond, is now in the United States and assisted with the preparation of the book for the press. May we express the hope that a free interchange of ideas between the botanists of England and France may soon return, meanwhile English readers will welcome the latest summary in English of the work of French cytologists on the cytoplasm of plant cells. F. C. Steward.

ANALYSIS OF MODERN STEELS

The Chemical Analysis of Ferrous Alloys and Foundry Materials

Modern Practice and Theory. By E. C. Pigott. Pp. xv+362. (London: Chapman and Hall, Ltd., 1942.) 28*s*. net.

The increasing use of alloy steels has produced difficulties necessitating modifications in the methods used in the analysis of plain carbon steels described in the older text-books; and in addition, considerable research has been required in order to simplify the estimation of the various additions, which now include many of the less common elements. The author, in the volume under review, has attempted to remedy the deficiency.

The scheme of the book is conceived on somewhat original lines. Each element is treated separately, and after describing its chemical and physical properties, and its role in steel manufacture, a consideration of the methods of analysis is given. This is followed by complete directions. An admirable feature is a very useful section dealing with the chemistry involved. This section, in particular, makes clear to beginners the fundamental principles underlying the various methods. This is too frequently disregarded in text-books of analysis. Many of the sections give evidence of careful investigation of various methods, more particularly those in which disputes are frequent. The chapter on the estimation of aluminium may be cited as an example; no reference is made, however, to the method in which most of the metals are removed by electrolysis using a mercury cathode.

The book also contains sections on the analysis of aluminium alloys, copper alloys and refractories. In none of these has the author been so successful. In the section on the analysis of aluminium alloys, it is perhaps incorrectly assumed that all the zinc is extracted by treatment with caustic soda. The silica estimation must also be made in nickel or platinum vessels, and not porcelain, since the attack by strong soda is by no means negligible. The estimation of iron and aluminium in copper alloys by precipitation with ammonia would also lead to high results for the latter element, due to the presence of zinc, if only one precipitation is made.

The method suggested for the analysis of refractories is in many respects open to criticism. The ignition of alumina requires a temperature of at least 1,100° C. and not 900° C. as specified. The single precipitation of magnesium as phosphate in the presence of such an excessive amount of sodium salts must lead to an erroneous result.

There are few adverse criticisms to make on the other portions of the book. The photograph of the carbon apparatus, however, is not marked with the letters used in the description, with the result the details are difficult to follow. In a future edition, the table on p. 345 could be extended with advantage by giving suggested methods for various types of steel.

The author has produced a most useful treatise which should prove of great assistance to all analysts who are already experienced in the methods of analysis of the older steels.

CHEMISTRY IN CLINICAL MEDICINE

Manual of Clinical Chemistry

By Miriam Reiner. Pp. xv+296. (New York: Interscience Publishers, Inc.; London: H. K. Lewis and Co., Ltd., 1941.) 3 dollars; 18*s*. net.

Methods of precision play an important part in modern medicine: they constantly seek, by the plain accuracy of scientific statement, to clarify clinical findings, to reinforce judgment, and to place opinion on a stable basis. Their proved value, proved by the work of an older generation, has broadened and amplified their place and scope, growth rapidly pushing forward with each new and accepted success. The present generation has in the physical, such as X-rays, and the chemical, such as the numerous tests whereby the intimate functions of the body metabolism can be observed, become familiar with new weapons which are now as much clinical necessities as a thermometer or a stethoscope. So far the field of value of such measures remains largely diagnostic and prognostic; the therapeutic application, without decrying the place of the exact control observations possible in many diseases, still rather lags behind.

Miss Reiner's little volume on the technique of the many chemical methods in everyday use comes from the Mount Sinai Hospital, New York, and certainly fulfils the standard which would be expected from a product of that institution. The book is first of all a manual, that is to say, it is a volume compact in make-up, but bold in print; systematic in arrangement but complete in adjuvant details; and of a size convenient to be propped up on a laboratory desk or thrust into a peripatetic pocket. The whole subject is fully, indeed generously, covered, ranging from specifications, indicators and measures to tests for the common poisons, vitamins and hormones. Adequate and proportionate space is given to the various function tests, gastric analyses, urine and cerebro-spinal fluid examinations, etc., the section on blood analysis being—and rightly so—the largest.

The method of statement of the procedure to be followed gives to each step of detail its corresponding line, thus gaining on one hand clarity of presentment and on the other being practical and time-saving. It is pleasing to note an insistence on exactitude of measures and times and on the technical details of the preparation of reagents.

Miss Reiner's book is obviously intended for an American audience and suffers, therefore, in trivial details in presentation to a British. With this slight reservation, the book can be cordially commended as a competent and careful piece of work fulfilling in every sense its aim. The bibliography has been wisely cut down to one or two references pertinent to each item. Joseph Geoghegan.

Practical Mathematics

By Clement V. Durell. Pp. viii+176+xv. (London: G. Bell and Sons, Ltd., 1942.) 3*s.* 3*d.*

THE intensive study of the principles of elementary mathematics has greatly increased with the coming of war and, as a consequence, a new type of book has made its appearance. The necessity of this lies in the fact that, in preparing for the technical branches of the Services, students have little time to study several comprehensive text-books. What they need is a single volume containing the essential arithmetic, algebra, geometry, trigonometry and mechanics, dealt with as tersely as possible and with a practical bias.

Mr. Durell's book meets these requirements and, as would be expected from this author, the treatment is lucid and the subject-matter well presented. The ten chapters amply provide the basic mathematical equipment needed by the students for whose use the book is especially intended. A larger space than usual—some twenty pages—has been devoted to tables but, in view of their value to practical students, it is somewhat surprising to find that tables of anti-logarithms have been omitted.

Elementary Qualitative Analysis

For College Students. By Prof. J. H. Reedy. (International Chemical Series.) Third edition. Pp. x+156. (New York and London: McGraw-Hill Book Co., Inc., 1941.) 10*s.* 6*d.*

THE fact that a third edition of this American manual on elementary qualitative analysis has been issued indicates the undiminished confidence and popularity in which this book is held in the United States. Moreover, it can be confidently recommended to teachers and students in Great Britain as a satisfactory work on qualitative analysis up to intermediate standard.

The book follows the conventional system of analysis for the common metals and acid radicals, but new methods and modifications of older methods have been included in certain cases as time-saving and reliable measures. The use of the centrifuge for facilitating the rapid separation of precipitates is of interest and might be more widely adopted. In addition to instructive details, the manual includes numerous exercises and questions, and is generally written in a style which will stimulate and hold the interest of a student starting on chemical analysis. The price, however, is likely to be too high for most students.

A New Scheme of Elementary Qualitative Analysis

By A. J. Mee. (Dent's Modern Science Series.) Pp. x+52. (London: J. M. Dent and Sons, Ltd., 1942.) 1*s.* 9*d.*

ANY departure from the well-trodden paths of elementary qualitative analysis is a sufficiently novel event to stimulate the interest of all chemists engaged in the teaching or practice of chemical analysis. In this little volume, Dr. Mee describes a new workable scheme for the detection and separation of the common metals, the principal feature lying in the fact that hydrogen sulphide gas is not required in the analytical separations. The poisonous nature and the difficulty of providing adequate supplies of hydrogen sulphide provide an additional recommendation for these new methods, which do not require any reagents not part of the normal stock of a chemical laboratory. For confirmatory tests with certain metals, however, special reagents are advocated, but the detection of acid radicals follows conventional lines.

The scope of this book broadly covers the requirements of students in qualitative analysis to intermediate standard. Teachers of chemistry are advised to obtain a copy of this book which is very moderate in price, and read it carefully; if there is something to criticize, there is also much to interest and stimulate.

Intermediate Quantitative Analysis

By Dr. A. J. E. Welch. Pp. iv+128. (London: University Tutorial Press, Ltd., 1941.) 3*s.* 6*d.*

THE small volume under review provides a course of practical exercises in quantitative chemical analysis up to intermediate and Higher School Certificate standard. Since the book is essentially designed to meet the requirements of examining bodies, the emphasis is largely on volumetric analysis, where the use of equivalents and normalities is strongly advocated. There is also a short but adequate section on gravimetric analysis, and many problems and exercises are to be found throughout the text. The book is very moderate in price and can be recommended as a worthy successor to "Elementary Quantitative Analysis" by Briggs and Bausor, which it now replaces in the University Tutorial Press series of text-books.

World Revolution and the Future of the West

By Dr. W. Friedmann. (Thinker's Library, No. 88.) Pp. x+118. (London: Watts and Co., Ltd., 1942.) 2*s.* net.

DR. FRIEDMANN, from an originally German and juristic standard, forecasts the fashion in which the present horrible chaos came upon us, and how the direct values should be secured. He is rightly concerned primarily and mainly with Western civilization. The globe has been humanized from the West, the Greco-Romans leaving their human structure to survive the revolutions which have led us to the present. Humanity, imperfectly indeed, passed the consolidatory Roman stage crowned by the glory of Greece. Then a further socializing covers the same ground in Christianity. Without the survival of these three—law, reason, beauty—humanity would not have come to the birth: laid as they have been in fresh revolutions to the present.

The legacy ensures the survival of socialization and lends itself from time to time to quiet lapses, as the eighteenth century, or scientific marvels, from the eighteenth century onwards. The British Empire has served and should still serve as the umbrella: one supposes that with the United States, an ultimate guarantee can be secured.

The main theme of Dr. Friedmann is what he calls the totalization of the West. He describes the methods by which, as in England, the desired advance is secured without conflict. The present crisis takes the form of securing to every individual sufficient to his needs spiritual as well as physical. One is bound to say that the standard of the spiritual is deplorably lowered on the way. The agency of a B.B.C. plants standards of taste far below what would be enjoyed if it continues to enforce the same with damnable iteration. There is a plain duty to lead upward.

It is pleasant to see that Dr. Friedmann, though obviously a communist in theory, lays the greatest stress on preserving as much freedom as consistent with the social fabric holding together. But a brave man will hesitate on prophecies in detail. The world conflict has still to be completed. F. S. MARVIN.

SOCIAL STRATIFICATION IN BRITISH SOCIETY

AT the extended general meeting of the British Psychological Society held at the Municipal Training College, Brighton, during April 9–12, the Section of Social Psychology arranged a symposium, under the chairmanship of Prof. M. Ginsberg, on the theme of "Social Stratification".

Prof. T. H. Pear, professor of psychology in the University of Manchester, read a paper on "Psychological Aspects of English Social Stratification". He began by pointing out that sociologists approach the subject of social stratification by making general statements about classes, comparing and contrasting them, but with very few illustrations from actual instances or research studies. This sort of specific information is regarded as rather a matter for journalists or novelists; but journalists and novelists are often biased by selection and personal preferences. Perhaps the roots of the difficulty lie deeper. Is it part of the general tendency of sociologists to eschew the concrete case—to be nomothetic instead of epigraphic ? Anyone who ventures into this area of psychology puts himself in a position to be shot at from both sides simultaneously. The subject of the symposium, therefore, is almost untouched by psychologists and attracts surprisingly little attention from sociologists. There are social forces which make it difficult for a professional thinker to regard his own position in society objectively, and fully to comprehend its meaning in a wider social pattern. Severe taboos are imposed upon detailed consideration of social status (especially of persons living in any but the 'top' and 'bottom' layers of society). This unanalysed acceptance of social status ('knowing one's place') partly explains the sociologist's and psychologist's neglect of social stratification. So English social psychology is, on the whole, an account by middle-class writers of middle-class behaviour.

English social stratification is not what it was in 1939 and it will change considerably when peace comes, according to Prof. Pear. It is, however, necessary to record that as in Disraeli's time there are still two Englands. From many directions we hear that after the War there will be great changes in the English social classes. In one sense this is a platitude. All modern wars cause social change; this is what they are fought for. Social stratification will be less, and the lines of demarcation less clear. At the beginning of this War, some urged that it should be fought for the 'English way of life', describing it in a manner which might be recognized by their friends, if not by the majority of the English. Since then, many have pointed out that no national way of life ever completely survives a great war; relatively few could wish our social structure to be exactly restored—cracks, moss, mildew and all.

Prof. Pear then went on to discuss social differences as shown by language. Each class uses characteristic terms of approval, disapproval, endearment, enthusiasm and boredom, and each disapproves or ridicules the choice of others. Euphemisms, too, are class-labels. Perhaps most of these are used by the middle (especially the lower-middle) class. Of the learnt phrases which especially indicate social strata the emollient group are the most striking. A good diplomat has many in stock, and knows when to produce the right one. They are used to begin, interrupt or end a conversation, to refuse or decline a request, suggestion or invitation; to correct a misstatement, to oppose a proposition without rancour, to adduce incontrovertible if unwelcome evidence, to accost a stranger, encourage a shy person or reprove a backslider. One social group may inaccurately attribute 'bad' speech to another. American journalists, when they 'quote' English working-class speech, are apt to write it without aspirates, yet in many parts of industrial England the 'h' is seldom dropped. With such warnings in mind, it may be said that difference in vowel-pronunciation is an important mark of social class. The Cockney modifies all the English vowels, usually transforming them into diphthongs. The auditory 'aspect' of speech is perhaps more important than the visual accompaniment, facial expression, gesture and posture. The comparative absence of facial expression and gesture from the speech-behaviour of the English 'ruling classes' may be a sign of social stratification.

On reading attempts made between 1918 and 1939 to explain war in terms of human experience and behaviour, Prof. Pear has been driven to conclude that most of them were conceived from an upper-class point of view. Underlying them is the assumption that when war is declared the author will take —or be holding—a commission. Few, especially those who 'explain' the stirring up of war in peace-time as due to aggressiveness, ask themselves how much the poorer people know about the nations for whom, after war has broken out, they are exhorted to feel emotions specified by the propagandists. In the past, privilege may have exercised good influences in many directions, yet during our lifetime its shortcomings have been increasingly obvious. To-day it seems to be falling into disfavour all over the world. Yet the difference ought to be clearly recognized between lessening privilege and decreasing tolerance of individual differences. Prof. Pear urged social psychologists to study social phenomena, both in the upper and the lower classes. For gentle manners are not the result of an accident, and he feels it would be a tragedy if we lost them.

Mr. Tom Harrisson, of Mass Observation, contributed to the symposium a paper on "Class Consciousness and Class Unconsciousness". There is no doubt that there are differences between different groups of the community, but after spending five years in making Mass-Observation studies of ordinary people in all parts of the country, he feels the extent of class difference has been exaggerated. Some sections of the community are richer or poorer, more or less educated, but the conception of clearly divided self-conscious groups is of doubtful validity. The class who are really 'class conscious' are the small upper-class group, who feel deeply aware of the mass of poorer and less educated people 'below' them, and often fear them. Many of the characteristics of 1942 Britain are due to this underlying 'fear of the masses' among our leaders, and their consequent tendency to treat working people as if they are somehow stupid and dangerous, to be kept in good humour but also to be kept in place. Among much the largest section of the community—the manual workers—there is little class consciousness; there are many divisions within the working class, as regards mentality and outlook. There are marked differences and conflicts, for example, within a cotton mill, and even within the team of three working on one cotton operation—the spinner, the side piecer and the little piecer.

This is not to say that there are not big differences between different sections of the community. But these differences are not necessarily *class* differences; there are often much bigger age or sex or temperament differences on the same subject. In general, the basic distinction is the amount of money owned or earned, and connected with this the degree of education. In observational studies of non-voting, over a series of municipal elections in which there were candidates of 'middle-class' and 'working-class' parties, it was found that 38 per cent of the so-called upper-class did not vote, 42 per cent of middle-class and 48 per cent of working-class. In a recent investigation on political attitudes, it was found that while most middle-class people were, for example, able to name at least one living Liberal politician, the majority of working people could not name one at all. Again, the degree to which people hold an opinion on propaganda films decreases sharply as one descends the economic scale. Many other examples could be given from Mass-Observation's researches, said Mr. Harrisson, to illustrate differences of knowledge and reaction between those who ended their education at the elementary stage and the better-off minorities. Cash differences inevitably produce other differences. But to term these indiscriminately 'class differences' obscures the fact that there are probably few inherent differences within the individual which cannot be eradicated in various ways, often quickly.

Mr. Harrisson thinks that the mental gulf between the upper classes and the working classes has been gradually exaggerated in the minds especially of the upper classes, though this does not make it any less significant psychologically for them. We have seen lately, in the rapid growth of works councils in war industry, how much can be done in a factory simply by bringing together around a table once a month some representative workers and managers. In the past most firms have assumed that the distinction between management and worker is absolute and essential; in war this distinction is found to be obstructive to maximum effort, and it has now been proved to be (to a considerable extent) avoidable.

Mr. Harrisson considered that the most useful symbol of British social structure is the familiar pyramid, with the King on the top, the mass of £3-a-week people at the base. There is a constant tendency among those at the bottom to try to climb up towards the top. The general tendency is to admire those at the top, seldom to resent them.

Mr. Harrisson described some ways in which working people in "Worktown" canalize our culture urge to go up the social scale. Every week-end Worktowners spend an extra quantity of money in special pleasures, such as drinking beer in the public lounge, where the *same* beer costs 1*d*. more than it does in the 'vault', used on week-days. During the week anybody wearing a bowler hat is either middle-class or a mourner. At the week-end, anybody and everybody may wear a bowler and look thoroughly middle-class. The week-end cycle is a regular process of class elevation, and men who never think of wearing a tie during the week may have a gold tie-pin on Sunday. Secondly, there is the cycle of the year, for which people save up every week, to take one week's holiday at Blackpool or elsewhere, generally at a much higher level of expenditure, environment and social prestige than they have ever enjoyed in their home town. One week a year they are able to live on a higher rung of the ladder.

Thirdly, there is the cycle of life. Many working people put aside money every week in their lives so that they can be buried with rich pomp and ceremony at their deaths. Moreover, the graves in Worktown cemetery are graded into four classes, according to the distances from the path and therefore the number of people who see your tombstone. Class I is very expensive and beside the main path. It is the ambition of many poor people to have in death a class position unattainable in life.

Prof. J. C. Flugel, assistant professor of psychology in University College, London, read a paper in the symposium on "Class Mind and Group Mind". He agreed with much of what Mr. Tom Harrisson had said. But we are forced to use the term 'class' because there is no better one available at present; in using it we must constantly remember that class is nothing rigid, but something very fluid. Psychologists have not tried to investigate the problem of class-consciousness systematically, though there has been a certain amount of work on racial and other attitudes. One is sometimes inclined to believe that the term 'class', as H. G. Wells remarks, has degenerated into a mere weapon or term of abuse. Class may be fixed by a class hierarchy, but otherwise it is difficult or impossible to define. Class fulfils only partly the criteria of McDougall's "highly organized group", that is: a group with a common purpose, continuity, some adequate idea of itself, interaction or rivalry with other groups, a body of common traditions, internal organization of the group, including specialization and differentiation. Marxism aims at bringing about an accentuation of these criteria, especially a common purpose, an adequate idea of the class grouping, and interactional rivalry. It assumes that there are only two classes and there will be an increasing dichotomy. In this Marxism has proved to be wrong, said Prof. Flugel; not only has 'class' become increasingly continuous, but also class distinctions are cut across by numerous other groups, the boundaries of which are drawn on other lines. Many workers are now small-scale capitalists; many in the general election of 1931 had the capitalist side of their feelings (fear about savings, etc.) accentuated so much that it swamped the workers' side (Labour sympathies, etc.).

Prof. Flugel felt that class distinctions are becoming more confused, rather than less, and that Marx's brilliant theory has not worked out in practice in Great Britain. Employers have increasingly sought to cultivate new loyalties within classes by profit sharing, bonus systems, welfare schemes, and so on. Then there is the rise of the manager in all his different grades; the increase of minor bureaucrats and officials; the small business man running his own business or shop, who may be more of a property owner than the salaried manager, but inferior in wealth to the skilled worker; such people feel interest in the nature of their business rather than their class.

Prof. Flugel went on to point out some changes in social stratification. A new sense of interest in and guilt about the conditions of the poor has occurred in the upper classes, and increasingly within the past few years. The realization of this responsibility is largely due to the rise of Socialism, but is also in opposition to Socialism. Then, working people have become more conscious of their increased opportunity to rise in the social ladder, though it is still limited. Workers want to belong to the upper class, rather than to destroy it.

Some connexions between social stratification and Freudian theory were finally suggested by Prof. Flugel. The upper class group compare, from the workers' point of view, with the 'ego-ideal'. This would explain to some extent three contradictory attitudes towards the upper class—the attitude of wanting to rebel against it, the attitude of wanting to attain it, and the attitude of wanting to submit to it. On the other hand, pure class-consciousness in the Marxist sense stresses only companionship in a continuation of the sibling relationship, the 'id'. But we also need the child-adult (parent) relationship, the 'super-ego'. Now all revolutions towards one class lead to dictatorships, and these are thereby socially unstable. A revolutionary movement can scarcely be as morally satisfying as a 'patriotic' movement.

Summing up, Prof. Ginsberg said that he felt the Marxist point of view, which he by no means wholly accepts, had been rather underestimated in discussion and that there are aspects of it which still throw light on present conditions. There is a certain reality in 'class', in so far as 'you feel at home' with somebody of your own class. There is much else that can be said; what is needed now is more thoughtful study.

ANIMAL HUSBANDRY IN INDIA*

By SIR ARTHUR OLVER, C.B., C.M.G.
Royal (Dick) Veterinary College, Edinburgh

IT would be quite impossible to gain a clear idea of the complexity of the problems facing animal husbandry in India without some understanding of the special factors conditioning the subject in India. For example : (1) Religious and traditional prejudices and customs. (2) Effect of the density of the population and the low purchasing power of the cultivators on farming practice. (3) General lack of appreciation of the fundamental principles which underlie proper breeding, feeding and management, and the great need which exists for a properly balanced system of land utilization. (4) Lack in most Provinces and States of any expert animal husbandry organization devoted solely to the interests of livestock. (5) Annual droving of millions of dealers' cattle from north to south of India.

Slaughter. The cow is a semi-sacred animal and must not be slaughtered. In strict Hindu communities, it is not permissible to give a merciful release even to a fatally injured and suffering animal. These inhibitions are productive of the most far-reaching difficulties and make it impracticable to carry on dairying or stock breeding on strictly commercial lines.

Castration. Until comparatively recently, stock owners were unwilling to castrate their cattle at an early age, though the males and females run together on village grazing grounds. This objection is now being overcome, and castration of inferior animals is carried out on a large scale by Provincial veterinary departments. It cannot, however, be too much or too often emphasized that no lasting progress can be expected in livestock improvement until arrangements are made for controlled mating, and for the proper feeding and management of breeding females and young stock.

Grazing areas. Though highly desirable, the improvement of such grazing areas as remain is not a solution of the cattle-feeding problem. The best of these areas tend to be taken up for cultivation, and in any event, cultivators ought to aim at devoting a portion of their holdings to fodder crop production ; thereby producing better stock and more milk, and helping to maintain the fertility and physical condition of the soil. Without such a change of system —where necessary—progressive degeneration of cattle seems certain to follow the gradual disappearance of good grazing lands on which the better cattle are at present bred.

Pinjrapoles and Gaushalas. The semi-religious pinjrapoles and gaushalas which are maintained in most cities throughout India have in many cases become anything but the homes of rest and comfort for derelict animals they are intended to be. By arranging for competent management and by breeding from the best of the cows and selling their milk, it has been shown that conditions can be greatly improved and profits made. Further, by taking up land for cultivation outside the city, the extra funds thus obtained can be utilized, to great advantage, to provide fodder crops and grazing for the hopelessly derelict and for the better feeding of the milking herd and young stock. By using selected sires, valuable young bulls were also produced, which should be of considerable value to breeders in the vicinity. These institutions could thus be made valuable demonstration centres all over India, and in addition to their great educational value, would save large numbers of quite good milch cows which are committed to their care.

Density of population. Owing to the smallness of the holdings and the low purchasing power of the individual, it has generally been considered impracticable for the Indian ryot to produce fodder crops for the proper feeding of his cattle, or to produce or purchase the increased supplies of milk which are essential for the health and proper development of the people. The tendency has been to consider that the only practicable policy is to produce more and more crops for sale or direct human consumption. As a result, soil fertility and humus content have been greatly depleted in many areas and enormous damage is being done by denudation, owing to removal of cover and humus from the soil. There seems, however, to be no reason why, by a suitable system of mixed farming, the ryots in suitable areas should not obtain as great money returns as under the present system of devoting their entire holdings to crops and, in addition, better stock and an invaluable supply of milk and dairy products for their families. Experiments undertaken to test this view have in fact shown that by substituting mixed farming, including milk production, for the mere raising of crops for sale, agriculture in many parts of India could be raised to a higher level.

Dung burning and the manurial value of livestock. Throughout the drier parts of India the custom of burning cow dung for fuel is a serious handicap to agriculture. A great deal of manurial value is lost ; the soil is deprived of humus ; and, as cattle are not usually herded on the land due for cultivation, the manurial value of their urine is also lost.

Moreover, under the present system, village grazing grounds become so trodden and infected with disease that it is impossible to breed or maintain any but the most stunted stock on them.

In the absence of available firewood, the burning of cow dung seems bound to continue, but it is clear that more of the manurial value could be made available for crop production if cattle were better fed and maintained on the holdings, wherever possible.

---

* Substance of a lecture before the India and Burma Section of the Royal Society of Arts, delivered on March 13.

Breeding practice and European cattle. Except among the expert breeders, who are dying out as the best of the grazing areas are taken up for arable cultivation, there is little tendency to ensure systematic mating to produce definite types, and one of the great dangers of importing European cattle into India is that the male cross-bred progeny are used indiscriminately as sires. It has now been shown that the better Indian breeds can easily be improved to a relatively high standard, by proper breeding, feeding and management. To control such work properly among the 200 million livestock of India, organized animal husbandry is, however, essential; thus it would take the place of these professional breeders. Otherwise sires of mixed or unknown parentage will be more and more used, though it is now well known that their progeny is very inferior.

Buffalo or cow. Much more highly fed as it usually is, the she-buffalo is generally considered to be a much more efficient milk and butter-fat producer than the cow, but a careful analysis of available data has shown that this is probably the case only where an abundance of coarse grazing is available. Indeed, strictly assessed in relation to the relatively high value in nutrition of the solids-not-fat of milk and with due regard to the need for a correctly balanced diet for the people, it is probable that for home production the balance would favour cows of the best Indian milch breeds. Under parallel conditions of feeding and management, such cows produce as much or more milk than buffaloes, and although the percentage of butter-fat is lower, the Zebu cow is highly efficient in converting dry crop residues into food of high biological value, and can even produce butter-fat as cheaply as the buffalo. For commercial dairying the buffalo has obvious advantages, but it is difficult to feel that the custom of maintaining she-buffaloes for milk production as well as cows for the production of working bullocks can be economically sound in rural areas.

Calf-rearing. In the case of buffaloes, the female calves are usually well fed and reared, while most of the males are allowed to succumb. In the case of cows the opposite happens, and in both cases it is the custom to present the stuffed hides to the cows at milking time to induce them to give their milk. In recent years it has been shown, however, that with proper handling when first brought into the milking herd, Indian cows yield their milk perfectly well without this, and that early maturity can readily be induced. It seems, therefore, that on agricultural holdings it would be sounder to use cows and feed them and both the male and female calves properly, instead of maintaining buffaloes as domestic milk producers and cows to provide the essential supply of work cattle. The custom of keeping cows in cities should also be discouraged, since it is insanitary and the cows—usually the best obtainable—are generally slaughtered at the end of the current lactation.

Dual- or single-purpose cattle. Judging from the limited success which expert breeders have obtained in Great Britain in their endeavours to produce cattle which are really efficient dual-purpose animals, for the production of milk and meat, it would probably be extremely difficult to produce breeds which would be efficient both for milk production and for the fast trotting or walking work which is the main purpose for which cattle are bred in India. With the rapid spread of motor transport the demand for fast trotting bullocks for road work is, moreover, rapidly decreasing, and with heavier ploughs it seems probable that slower moving cattle may in future be more acceptable to cultivators. A strong view is, however, held among them, from north to south of India, that capacity for fast work and high milk production do not go together. In any event, in view of the very striking improvement which has in recent years been effected in the milk yield, early maturity and docility of pure Indian dairy cattle, it seems certain that the best of these breeds will be developed to still higher levels. Milk recording and the publication of milk records has been undertaken by the Animal Husbandry Bureau to this end.

Annual droving of dealers' cattle. The droving of immense numbers of dealers' cattle from north to south and east to west of India involves constant danger of spreading contagious disease of all kinds, and protective inoculation of such cattle should so far as possible be enforced.

Animal husbandry departments. Embracing as it does about one third of the domesticated animals of the world, animal husbandry in India is obviously a huge undertaking, the development of which on modern lines requires much more extensive Government provision, independent of the requirements of cash crops, than has so far been made available.

It is not possible in the limited space at my disposal to discuss all the measures which were taken during my eight years as animal husbandry expert to place the various branches of animal husbandry in India on a better footing. From the first it was obvious that in view of the crippling losses from disease, malnutrition and similar causes, far more comprehensive Government expert assistance to stock owners was required. Every help was accordingly given by the Imperial Council of Agricultural Research to the reorganization of the Mukteswar Research Institute as (1) a research station in the hills, with staff and facilities for dealing in appropriate sections with all branches of veterinary research, and (2) a plains station for the production of biological products on the very large scale which is needed, and for research which can be satisfactorily carried out in the plains. The research staff at Mukteswar was organized in appropriate sections, each capable of dealing with a branch of veterinary research, and the substation at Izatnagar was provided with additional sections to deal with animal nutrition, poultry and poultry diseases, and genetics, in addition to the production of biological products. In this way a very comprehensive animal husbandry research and production institute was built up, and to provide the necessary link between research and the field work of Provincial veterinary departments, a veterinary investigation officer was also provided by the Imperial Council of Agricultural Research for each British Province and certain affiliated Indian States. These have been found of great value both to research and in the systematic study of local disease problems, and have now been made a permanent part of Provincial and State disease control organizations. Stockmen, capable of carrying out inoculation and first-aid treatment, after suitable training at veterinary hospitals, were also arranged for. The facilities for disease control and animal husbandry have thus been improved and research plans facilitated both at Mukteswar and at veterinary colleges, and during the past decade our knowledge of disease conditions and of the incidence of disease has been greatly increased.

The standard of veterinary education and technical training was improved at most veterinary colleges, and arrangements have recently been made to institute a B.Sc. university degree course at the Madras Veterinary College, in conjunction with the four-year veterinary graduates course. This is a welcome move in the direction of higher veterinary education, which is much needed in India.

Much attention was given to the improvement of dairying in India; this topic has been dealt with exhaustively by Dr. Norman Wright, who was brought out to give expert advice on the many and difficult problems which have to be faced by this industry under Indian conditions. Attention was also given to the control of disease among equines and to the improvement of local breeds of horses and donkeys; the breeding of horses was in the main provided for by a military organization, in the operations of which the Imperial Council of Agricultural Research had no say.

The nucleus of an Animal Husbandry Bureau was also formed and all the information available in the records of military dairies, dairy farms and similar institutions was extracted and published. By this means the great potentialities of pure-bred Indian cattle in regard to milk production was for the first time made generally known, and in combination with the publication of milk records, has acted as a great stimulus to the improvement of pure Indian milch breeds.

Authoritative definitions of the breed characteristics of several of the best-known breeds of Indian cattle were also taken up by the Bureau and have since been published; and a village survey was carried out, in four areas in different parts of India, with the view of ascertaining precisely the amount of milk and other dairy products produced and consumed by the Indian ryot.

A co-ordinated scheme for the improvement of the sheep of various parts of India was instituted by the Imperial Council of Agricultural Research, and a representative was sent to South Africa to obtain first-hand information with the view of considering the possibility of establishing an Angora goat industry in certain parts of India where similar goats already existed. Some assistance was also given to the improvement of village goats and poultry.

The main problem of animal husbandry in India is the improvement of the working bullock, and one of the most important measures taken to improve livestock was the organization in 1938 of the first All-India Cattle Show at New Delhi, at which representatives of the most important breeds of pure Indian Zebu cattle were exhibited for the first time in history. Such a central show is a logical development of the annual shows which are held in many Provinces and States, and at which local cattle are judged and prizes given, each year. These shows are a part of the measures taken by Provincial Governments to secure systematic improvement of livestock and have proved of the greatest value in suitable areas. If properly followed up, the central show should serve to advertise to the world that, for tropical countries, Indian Zebu cattle have no equals.

As it covers no less than about one third of the domesticated animals of the world, animal husbandry in India obviously requires much more extensive Government provision, apart altogether from the requirements of cash crops.

X-RAY ANALYSIS OF HÆMOGLOBIN

By M. F. PERUTZ

Cavendish Laboratory and Molteno Institute, Cambridge

It has been shown that very detailed X-ray diffraction photographs can be obtained from crystals of horse methæmoglobin suspended in concentrated solutions of ammonium sulphate. On rapid drying in air, these crystals contract by 42 per cent of their wet volume. The dried crystals give a poor diffraction pattern consisting of few low-order reflexions around the central spot[1].

A method has now been developed whereby it is hoped greatly to extend the information which X-ray photographs from single crystals of proteins have yielded up to the present. It is based upon a suggestion first put forward by Bernal, who observed that after the transition of chymotrypsin crystals from the wet to the air-dried state, the shrinkage is accompanied by alterations of the relative intensities of reflexions. Bernal concluded that if it were possible to obtain complete sets of reflexions in different states of hydration of the crystal, then this may enable us to distinguish between the effects of intra- and inter-molecular scattering and, eventually, to compute a direct Fourier synthesis of the molecular structure of the protein[1].

Single crystals of horse methæmoglobin can be made to contract so slowly that the complete drying process occupies several days. In addition, it was found possible to arrest the contraction over periods of weeks at stages of hydration intermediate between the wet and the air-dried, leaving sufficient time at each stage to record the reflexions from the principal crystal zones. So far the following results have been obtained:

(*a*) *Cell dimensions and optical properties.* Horse methæmoglobin crystals are monoclinic and belong to the space group $C2$, with two molecules in the unit cell. The cell dimensions at various degrees of contraction are given in the accompanying table. It is seen that b stays constant throughout the contraction, while a does not change until the final stage 4, when it suddenly shrinks from 109 A. to 104 A. The most important variable is the c spacing, which contracts by a total of 29 per cent. The angles between the optical extinction directions and the a axis remain unchanged during the transition from stage 1 to stage 2. At stages 3 and 4 the crystals had become too opaque for optical examination.

CELL DIMENSIONS AT DIFFERENT STAGES OF SHRINKAGE

Stage of shrinkage	a	b	c	β	$c \sin \beta$	Volume (A.^{3})	Contraction per cent
1 Wet	109 ± 0·5	63·8	55·1	111·1	51·4	357,000	—
2 Intermediate	,,	,,	51·4	116·2	46·1	321,000	10·3
3 ,,	,,	,,	53·5 ± 0·3	127·5 ±0·5°	42·3	294,000	17·7
4 Air-dried	104 ± 1·5	,,	54·1 ± 1·0	137·5 ±1°	36·5 ± 0·5	242,000	32

Probable errors are given wherever they exceed 0·2 A. or 0·2°.

(*b*) *Changes of diffraction pattern.* Shrinkage of the crystals has the effect of increasing the intensity of the diffuse background relative to that of the Bragg reflexions; it also causes the latter to fall

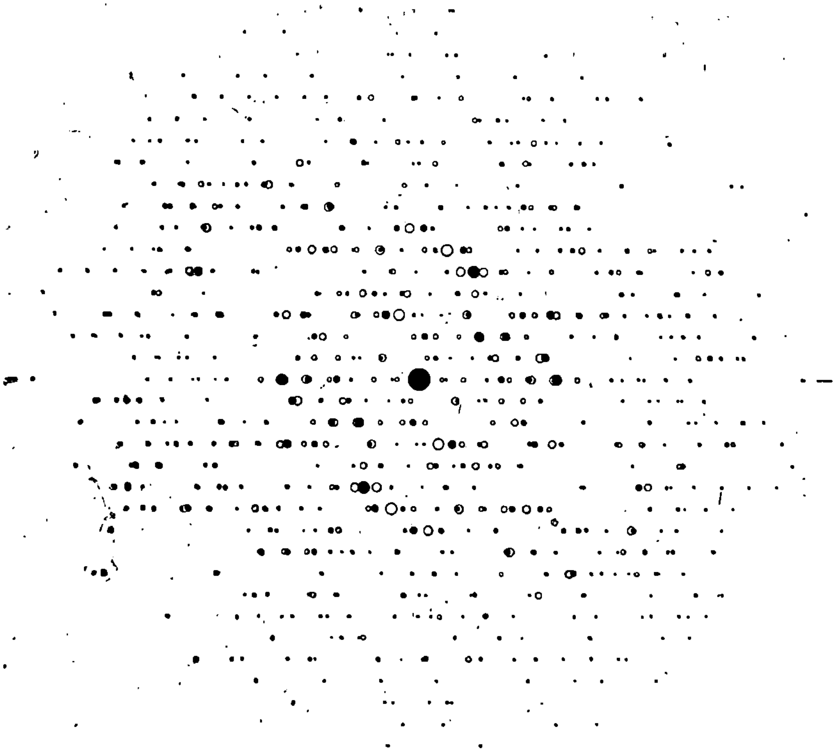

Fig. 1.

Distribution of F'^2 in the reciprocal lattice plane $h0l$.

The large circle in the centre is the origin. The c^* axis is horizontal.

off more rapidly at larger angles θ. While the patterns at the two intermediary stages show almost as much detail as those obtained from wet crystals, all reflexions of spacings smaller than 7 A. vanish in the case of the air-dried crystals.

The greatest changes in the relative intensities are to be expected in the $h0l$ reflexions, since all contraction takes place in the b plane. Fig. 1 consists of the superimposed pictures of the reciprocal lattice planes $h0l$ for the stages 1 and 3 respectively. The blank circles are drawn at the reciprocal lattice points belonging to stage 1, the blacked circles at the appropriate points for stage 3. The areas of the circles are proportional to F'^2_{h0l}. A temperature factor of $e^{-60\sin^2\theta/\lambda^2}$ was applied to the F'^2 values for stage 1, so as to adapt their rate of falling off to that observed at stage 3. It will be noted that there exist definite regions in reciprocal space where F' tends to have high values and others where it tends to vanish, and that these regions tend to occupy identical positions with respect to the origin and the c^* axis, irrespective of the degree of shrinkage.

(*c*) *Patterson-Fourier projections* on the b plane have been prepared for the stages 1, 2, 3 and 4. Those for stages 1 and 3 are illustrated in Fig. 2. If these two maps are superimposed so that the centres and the a axes coincide, then the positions of the majority of peaks also coincide. Moreover, the peaks show striking similarities in shape. If several unit cells are drawn of each of the two projections and the two large maps so obtained are superimposed with their a axes and one row of origins coinciding, then the effect shown in Fig. 3 is seen. The map can be divided into regions which are parallel to the a axis. Proceeding from the line of superposition (A in Fig. 3) there is first a region where both the maxima and the outlines of all major peaks coincide (region AP or AQ). Next comes a region where the correspondence between the outlines gradually vanishes and where the peaks which belong

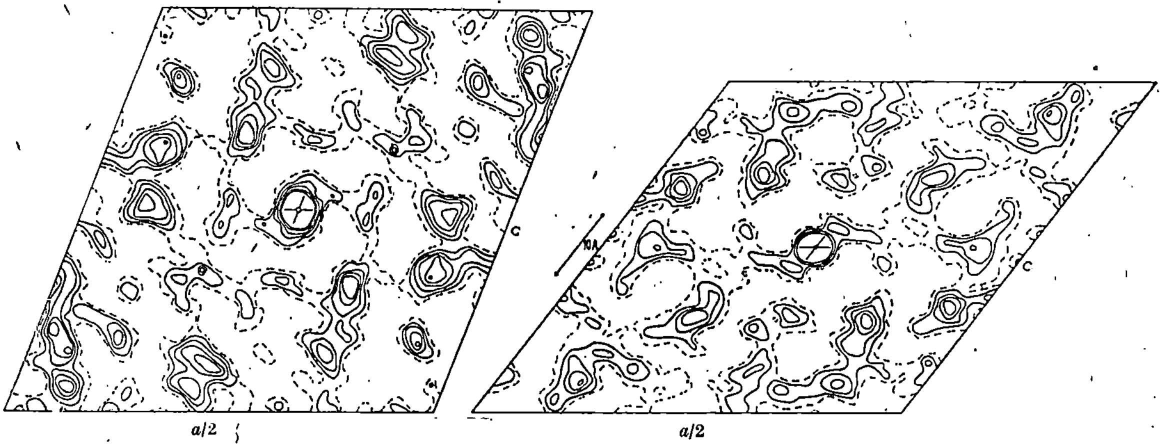

Fig. 2.

(*a*) Patterson (x,z) prepared from $F'^2_{h0l} \cdot e^{-60\sin^2\theta/\lambda^2}$ of stage 1, wet crystal; (*b*) Patterson (x,z) prepared from F'^2_{h0l} of stage 3, partially dried crystal.

In both diagrams the contours are drawn at intervals of 50 and the negative contours are omitted. The dashed line is the zero contour. The higher contours near the origin are omitted and the origins are marked by axial crosses.

to the contracted crystal tend to be displaced towards the line *A* (shaded region *PR* or *QS*). Finally, beyond this second region, no relation exists between either the outlines or the positions of the peaks (beyond *R* or *S*). The first of the three regions extends to a spacing of ~15 A. from the line of superposition, the second from 15 to ~21 A. It should be noted that no reflexions with spacings smaller than 3 A. have been used for the Fourier summations and that in consequence the maps cannot reveal any detail smaller than 1·8 A.[2]

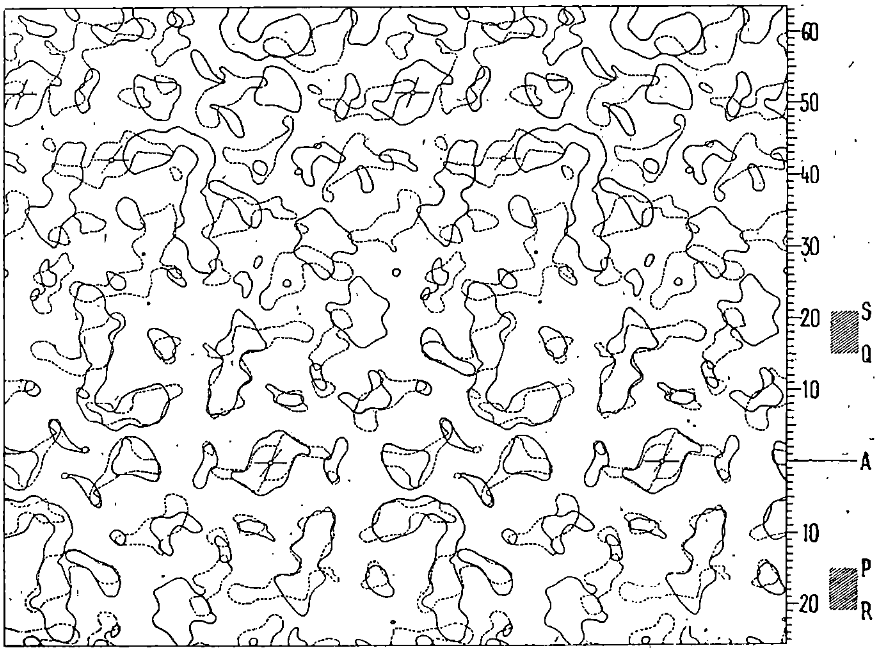

Fig. 3.

Superposition of several unit cells of each of the diagrams shown in Fig. 2.

All contours with the exception of the + 50 contour are omitted. The full contours and crosses correspond to the wet crystal (Fig. 2a), the dashed ones to the partially dried crystal (Fig. 2b). *A* marks the line of superposition and is parallel to the *a* axis. The scale is in A.U. The diagram shows only the outlines of the major peaks and not their maxima.

The results lead to the following conclusions concerning the molecular structure of hæmoglobin:

(I) The rigidity of the crystal along the *b* axis shows that the molecules must be linked together in this direction. Each of the two molecules in the cell lies on an axis of twofold symmetry parallel to *b*. Hence the diameter of the hæmoglobin molecule in this direction must be equal to the length of the *b* axis, that is, 64 A.

(II) Optical and X-ray data go to show that throughout the shrinkage the hæmoglobin molecules maintain their orientation relative to the *a* and *b* axes, despite the very great changes in the angle β. This orientation can be maintained only if the molecules form coherent sheets extending through the crystal parallel to the *c* plane, with layers of water and probably ammonium sulphate between the protein sheets. On drying, the layers move together and simultaneously slip over one another, thereby increasing the monoclinic angle (Fig. 4). Additional evidence for the existence of a sheet structure is the tendency of the crystals to break up into fragments parallel to the *c* plane under various conditions leading to dissolution or denaturation.

(III) Certain conclusions could be drawn concerning the thickness of the protein sheets, that is to say, the distance apart of two neighbouring water layers, if it could be decided which of the peaks in Fig. 3 are definitely of intramolecular origin. It can be shown that if two corresponding peaks at different shrinkage stages coincide and are closely similar in shape, then it is highly probable that they belong to the intramolecular type. On the other hand, if two peaks do not coincide, it does not necessarily follow that they are not of the same type. Thus we can be reasonably certain that the peaks in the region *AP* (0–15 A.) are all intramolecular, but no decision is possible as regards most of the peaks beyond 15 A. In consequence, it is certain that the distance apart of two neighbouring water layers is greater than 15 A. On the other hand, it cannot be greater than 36·5 A., as this is the *c* spacing in the air-dried crystals. Furthermore, each molecule lies on an axis of twofold symmetry. These conditions limit the number of possible arrangements to two. Either the hæmoglobin molecule must consist of two sheets of protein of 18 A. thickness each with one layer of water and possibly salt in between, the two sheets being related by a twofold axis, or it consists of a single rigid sheet of 36 A. thickness, the sheet itself possessing twofold symmetry. No decision between these two possibilities can be made at the moment.

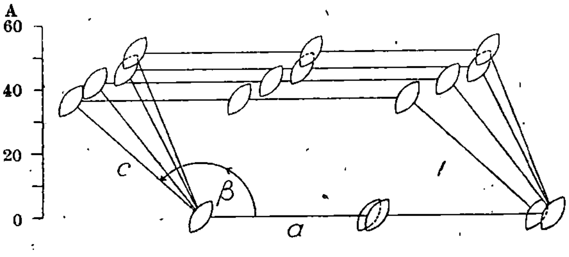

Fig. 4.

Changes in cell dimensions during successive stages of contraction.

The positions of the diad axes are marked; each of these is associated with one hæmoglobin molecule. The protein sheets mentioned in the text lie parallel to the *a* axis and normal to the plane of the paper.

(IV) The dried hæmoglobin molecule is seen to be a platelet 36 A. thick; it is 64 A. long in the direction of *b* and probably somewhat shorter along *a*. Elongated ellipsoids of axial ratios 1 : 4 or 1 : 5, such as those proposed by Polson[3] and Neurath[4], are incompatible with the crystal structure.

Full details will be published elsewhere.

I wish to thank Sir Lawrence Bragg for all he contributed to this research in many discussions on the problem and for his constant help and encouragement; also Prof. D. Keilin, who helped me to overcome many of the difficulties I encountered while growing the crystals, and gave me much stimulating advice. I am grateful to the Rockefeller Foundation for the grant which makes this research possible.

OBITUARIES

Prof. Jean B. Perrin, For. Mem. R.S.

It was with great regret that I saw the announcement of the death in New York on April 17 of Prof. Jean Perrin. He had many friends in England who will feel that we have lost a staunch ally, for it will be remembered that during the War of 1914–18 he was of the greatest assistance to every one engaged in scientific work for the Government departments. He was himself scientific adviser to the French Government, and was keenly interested not only in what was being done in Paris but also in the work done in England, especially the development of tanks. He disliked the Germans very much, and during the whole of the period 1914–18 and shortly before this War broke out the spirit that animated him was "Il faut écraser les Boches". It was some consolation to know that he and his son had got out of Occupied France and gone to the United States.

Early in his scientific career, more than forty years ago, Perrin was elected professor of physical chemistry at the Sorbonne, and since then he has made many original investigations in atomic physics, for which he will always be remembered, as they are included in all modern treatises on these subjects.

Perrin's earliest experiments were designed to determine the nature of cathode rays and the conductivity of gases produced by the action of Röntgen rays and radioactive substances. At that time Varley and Crookes maintained that the cathode rays were material particles charged with negative electricity, which were repelled from the cathode and acquired large velocities under the action of the electric force. But the early experiments which were made to detect the charge were inconclusive, and other physicists maintained that the rays were a form of undulatory motion of the ether. The problem of determining the nature of the rays was settled by Perrin, by experiments with apparatus which showed conclusively that the rays were charged negatively.

But the work for which Perrin is best known is his experimental investigation of the Brownian motion. This investigation was designed with the object of determining the energy of agitation of molecules, from which it is possible to deduce the number of molecules in a cubic centimetre of a gas. There were several indirect methods of estimating that number but the results varied within wide limits. Perrin in his method of determining the number relied on a general theory of motion of particles, which implied that the mean energy of agitation of small particles suspended in a liquid was the same as that of a molecule of a gas. He succeeded by very remarkable original methods in determining the energy of agitation of the particles and thus deduced the number of molecules in a cubic centimetre of a gas.

Perrin's work "Les Atomes" is one of the most popular scientific publications. It deals with the discoveries made in molecular physics during the very active period after the discovery of Röntgen rays and radioactive substances. Before the 1936 edition came out, 30,000 copies had been sold. He also wrote a very interesting book in 1935 entitled "Grains de matière et de lumière", where he gave a most vivid account of modern theories of radiation, and discussed several problems which agitate the minds of physicists.

Perrin never seemed to change; he was just as lively and original in his conversation a few years ago as he was when he was first appointed to be professor at the Sorbonne. He took the greatest interest in young people engaged in research, and had a party for them once a week in his laboratory where discussions took place on all sorts of subjects. What was most pleasant about these meetings was the boyish interest Perrin took in experiments, for he always placed more confidence in experimental investigations than in mathematical theories.

When on one occasion another professor, after trying to persuade him to accept a theory he had propounded, said "At least you must admit there is something in it", Perrin replied: "My dear ——, it would be difficult to propound a theory that was entirely false."

He will be greatly missed by all French men of science, and also by his friends in England, for nothing added so much to the pleasure of a visit to Paris as a meeting with Perrin.

J. S. TOWNSEND.

Dr. T. B. Macaulay

THOMAS BASSETT MACAULAY, whose generous benefactions made possible the foundation of the Macaulay Institute for Soil Research at Aberdeen, died in Canada on April 3.

Mr. Macaulay who was born at Hamilton, Ontario, on June 6, 1860, was descended from the same family as Macaulay the historian, the Macaulays of Uig in the Island of Lewis. His grandfather migrated to Aberdeenshire and his father, Robertson Macaulay, was born at Fraserburgh in that county, but went to Canada as a young man and later became president of the Sun Life Assurance Company of Canada.

Dr. T. B. Macaulay entered the service of that Company in 1877, and held the posts of actuary, secretary, director and managing director, finally succeeding his father as president. He played a great part in expanding the Company from a very small concern to one of the most important corporations of its kind in the world. He was a fellow of the Institute of Actuaries of Great Britain and a charte member of the Actuarial Society of America of which he was twice president. A leading figure in his profession, he received the honorary degree of LL.D. from the Universities of McGill, Edinburgh and Aberdeen.

Dr. Macaulay's interests outside insurance wer widespread and ranged from the development o trade between Canada and the West Indies to medica research and agriculture. During the War of 1914–1 he was Canadian chairman of the National Committe on Food Resources. He had the experimenting instinct highly developed. On his own farms at Hudso Heights near Montreal he built up one of the fines Friesian herds in North America, and for many year carried out experiments on the development of strain of maize and soya beans with the view of obtainin early varieties of good quality suitable for Canadia conditions. The work was not delegated to othe but was carried out personally by this busy business man in his limited leisure. The success which he achieved in his experimental work showed that had he elected to become a professional scientist he would have been as eminent as he was in his chosen profession.

Dr. Macaulay contributed generously to numerous causes both in Canada and Great Britain. In memory of his forebears he gave many thousands of pounds for educational, hospital, welfare and other purposes in Lewis and in Fraserburgh, but his benefactions were national as well as local. He was interested in genetics and in research on the endocrine glands, and contributed large sums to the Animal Breeding Research Department of the University of Edinburgh. Probably he will be remembered best as the founder of the Soil Research Institute at Aberdeen which bears his name. The buildings and equipment, including a demonstration farm on peatland in Lewis, were provided by Dr. Macaulay on the understanding that the Government would meet the cost of maintenance. He possessed tireless energy and unbounded enthusiasm. One of his ambitions was to bring about an improvement of the poorer classes of land in Scotland and during his visits to the country much of his time was spent in furthering this object. His influence with the crofters in Lewis was very great and he succeeded in bringing about many improvements where others had failed. The results of peat reclamation experiments carried out in Lewis were later applied by the Macaulay Institute in the successful reclamation of peatland in Lanarkshire on behalf of the Commissioner for the Special Areas.

It was my privilege to become one of Dr. Macaulay's friends and to stay with him several times in Canada, where I saw something of his happy home circle and of his scientific pursuits. He was a man of great sincerity and strength of character, kindly and always anxious to help his fellows. He lived simply and gave generously.

It was a source of great satisfaction to him during his last visit to Great Britain four years ago to stay at the Institute which he was instrumental in found- ng and to see the realization of some of his cherished ambitions.

W. G. Ogg.

Mr. F. J. Selby, C.B.E.

Mr. Francis James Selby, C.B.E., one of the mall band of workers who formed the staff of the ational Physical Laboratory in its early days nd helped to develop it from small beginnings o an institution of world-wide renown, died on arch 5. He joined the staff in 1903 to take charge f the prediction of tides which the Laboratory was bout to carry out for the Indian Government, and o establish a Division for Optics to supplement the ork of the Observatory Department at Kew. elby was also secretary to the Director, an office hich, if the range of his activities were considered, ould have been better described as secretary of e Laboratory. In this position, which he made e of great importance in the Laboratory organiza- on, he took a large share of administrative respons- ility. His sympathy with the policy of Sir Richard azebrook particularly fitted him for this work, and ose who knew the Laboratory well realized that it s no less fortunate in its secretary than in its first rector. Everyone trusted him and valued his dgment and advice.

In 1909 Glazebrook was appointed chairman of the newly formed Advisory Committee for Aeronautics; Selby was chosen and continued as secretary until 1919, when the committee was replaced by the Aeronautical Research Committee. His services were recognized by the award of the C.B.E.

In 1918, shortly before the Government accepted financial responsibility for the Laboratory in place of the Royal Society, the office of Secretary of the Laboratory was formally established, with Selby as the first holder. In the following year Sir Joseph Petavel became director, and Selby continued to give most loyal service. He retired in 1932 on reaching the age of sixty-five.

Selby's special training was in mathematics, first at University College, London, where he greatly appreciated the teaching of Karl Pearson, and afterwards at Trinity College, Cambridge. He graduated as sixth wrangler in 1891 and later became mathematical master first at Bristol Grammar School and then at Repton. At the Laboratory, Selby retained a keen interest both in mathematics and in education. There was probably no important paper on relativity or the quantum theory that he did not read critically. He took an active interest in the further education of junior members of the Laboratory staff.

On his retirement, Selby intended to write a history of the early days of the National Physical Laboratory, a task for which he had unique qualifications. Unfortunately, little more than two years after his retirement, when the work was only partly done, he had a stroke and his memory was affected to an extent which made the completion of the history impossible.

Selby was twice married, and is survived by a daughter.

T. Smith.

Mr. C. Oldham

Charles Oldham was born at Lincoln on April 16, 1865, but at the age of six the family went to live at Sale in Cheshire. It was at the preparatory school there that began the life-long friendship with T. A. Coward that was later to bear fruit in the classical account of the "Birds of Cheshire".

Until his retirement in 1927, the claims of his professional duties as assistant manager of the Manchester office and later of the London office of the Commercial Union Insurance Company, permitted him little leisure to pursue his scientific studies. Despite this temporal handicap, he became an acknowledged authority on British malacology and ornithology. He it was who contributed the field notes for the first edition of Witherby's "Handbook of British Birds", and he made notable contributions to the study of British land and freshwater Mollusca and especially in the critical genus of the Pisidia, his specimens of which are now in the national collection. It is at once a tribute to his characteristic thoroughness and physical endurance that, in the course of the study of this group, he examined almost all the very large number of tarns in North Wales.

Oldham was a field naturalist of the best type, outstanding alike in the accuracy of his observations and the breadth of his knowledge, and by no means the least valuable of his services was his influence upon those with whom he came in contact. For ten years Oldham was one of the honorary secretaries of the Hertfordshire Natural History Society and its president in 1920. His annual reports on the birds of that county were models of discriminating observation. For twenty-three years he was treasurer of the Conchological Society and he served as vice-president of the Linnean Society, the Ray Society, the British Ornithological Union, the Malacological Society, the British Ecological Society, and on the committee of the British Ornithological Club.

Like all men who possess not mere ability but also wisdom, Oldham was essentially modest and his published papers, though numerous and valuable, are but a poor indication of the profundity and wealth of the knowledge that was so freely placed at the disposal of others. To accompany him in the field was to enjoy a liberal education and to share the riches of a well-plenished mind, whilst the privilege of his friendship was both an inspiration and a stimulus. His loss to science is the greater because in these days of "learning more and more about less and less", the number of those who combine the insight of the specialist with a balanced perspective is growing fewer although the need for them increases.

E. J. SALISBURY.

WE regret to announce the following deaths:

Lieut.-Commander L. C. Bernacchi, who wa physicist to the Southern Cross Antarctic Expedition, 1901–4, on April 24, aged sixty-five.

Prof. H. L. Bowman, Waynflete professor of mineralogy and crystallography in the University of Oxford, on April 22, aged seventy-seven.

Dr. Arthur Michael, emeritus professor of organic chemistry at Harvard University, on February 8, aged eighty-eight.

Prof. Carl Oppenheimer, editor of *Tabulæ Biologicæ*, *Enzymologia* and author of well-known books on biochemistry, aged sixty-seven, on December 24, at The Hague.

Colonel M. O. Tandy, O.B.E., formerly of the Survey of India, on April 18, aged sixty-eight.

Dr. W. E. Thrift, provost of Trinity College, Dublin, and formerly Erasmus Smith professor of natural and experimental philosophy in the College, on April 23, aged seventy-one.

NEWS and VIEWS

Planning and Rebuilding in Britain

IN his first official statement in the House of Lords as Minister of Works and Buildings, Lord Portal emphasized that the policy initiated by his predecessor, Lord Reith, still holds good. Lord Portal was replying to inquiries by the Bishop of Winchester, who voiced the wide anxiety as to whether the recent changes at the Ministry of Works and Buildings meant a change in the Government's intentions. He emphasized that unless planning took a prominent place in housing reconstruction, there would be chaos through the rivalry of competing authorities and uneconomic use would be made of the land, with the attendant spectacle of distressed areas.

Lord Portal explained that the broad objective of the new Ministry would be the right use of the land of Great Britain for all purposes. The Minister would have the responsibility of seeing that policies in regard to agriculture, transport, etc., were properly co-ordinated. Further legislation will be introduced in the light of reports to be submitted very shortly by Mr. Justice Uthwatt and Mr. Justice Scott. Considerable reduction in the number of planning authorities has already been made by voluntary arrangement. Lord Portal also said he is working in close collaboration with the Paymaster-General in considering the relation of planning to the need for the preservation of areas of natural beauty and especially the coastline. With regard to the building industry, it would be essential that, directly the War ends, the industry should be ready, through organization, to cope with the demands which would be made on it. The personnel of the industry would have to be dealt with on a new basis.

The Central and Supplementary Registers

THE Minister of Labour stated last winter that it was proposed to merge the Central and Supplementary Registers in a new Appointments Department of the Ministry of Labour and National Service. This has now been done. The Central Register covers those with scientific and technical qualifications, while the Supplementary Register includes those with administrative and managerial qualifications and others, not on the Central Register, with scientific and professional qualifications. It is stated that there is now a lack of men in nearly every branch covered by the Central Register. As regards the Supplementary Register, every effort will be made by the new Appointments Department to make the best use of the varied qualifications which are represented. The Register will be revised at intervals of two months, and it is intended to arrange personal interviews with all those whose names are on it. It will be decentralized to some thirty appointments offices outside London, all of which will be linked with the Appointments Department in London at Sardinia Street, Kingsway, W.C.2. The Centra Register is being moved to the same address. These Registers, if properly handled, should prove of immense value in assessing the professional resources of the country for both present and future needs.

Association for Planning and Regional Reconstruction

THE Association for Planning and Regional Reconstruction, Ltd., is incorporated as a limited company not for purpose of profit, and its board is responsible for the direction and co-ordination of research into post-war problems. While the polic of the Association is to co-operate with individuals organizations and local and national authorities, it does not itself undertake direct works of reconstruction. Its object is to serve as a centre for research for which purpose it employs a small trained research staff, and to advise and to suggest, as well as t correlate experience. It also endeavours to train nucleus of men and women in the technique o planning in its broadest sense. The work of th School of Planning and Research for Nation Development is now carried on through the Association.

The Association has issued a series of four-pa broadsheets setting out simply and concisely th results of each piece of research. Of the broadshee so far issued, one contains general information regarding the work of the Association and others deal with the distribution of fresh food, human wastes, their collection and disposal, and a summary of existing methods of disposal. The first of these outlines a system of fresh-food production and distribution, assuming a network of 'control farms' and 'fresh food centres'. Those on human wastes summarize suggestions as to how such wastes can be used to maintain soil fertility, and give a technical analysis of present systems of disposal. The Association is also engaged on the preparation of a series of maps, designed to present existing statistical and other information on various problems in visual form. It is also studying the problems of a service to promote positive health and the lay-out of a 'health centre', standards governing housing density, prefabrication possibilities in housing construction, and the marketing of goods in relation to planning.

Scientific Data in Glass Technology

In his presidential address to the Society of Glass Technology, delivered on April 14, Dr. S. English discussed "The Commercial Use of Scientific Data". After a brief review of the rapid development of the science of glass technology during the past twenty-five years, and the importance of the results obtained in their application to manufacturing processes, the problems of illuminating glassware of the diffusing type were considered in detail. Three essential requirements of such glassware are that it should be (1) practicable from the manufacturing point of view, (2) technically correct from the illuminating point of view, (3) artistically correct. The problem of glare was emphasized in relation to the adaptability of the human eye to an enormous range of illumination intensities from 2,000 to 4,000 ft.-candles on a bright summer day to 0·002-ft. candles for A.R.P. lighting. Diffusing glass envelopes reduce the glare and increase the detail comprehended by the eye by removing the intensely bright source from direct vision.

The properties of completely diffusing opal glasses in conjunction with metal filament lamps were then described. In general, the percentage transmission of opal glasses is always higher for directed light than for diffused light (2·5 per cent increase). The proportion absorbed is always less for directed than for diffused light, by approximately 1–5 per cent, and the proportion reflected is usually less for directed than for diffused light. Examples were given of the use of physical data for the predetermination of the performance of a lighting fitting made in flat opal glass plate, illuminated on one side by a single electric filament lamp, with and without a second plate behind the lamp to serve as reflector, and of a complete opal sphere enclosing the lamp. The efficiency of an opal sphere as a lighting unit depends on the glass, which must be a perfect sphere of uniform thickness, with no neck opening, and giving perfect diffusion of transmitted and reflected light; and on the lamp, which must give a uniform light distribution. The view was expressed that the British illuminating glassware industry should endeavour to provide the whole of the post-war requirements of Great Britain in this field.

Jig Borer Microscope

The recent introduction of the "Watts" jig borer microscope provides a valuable optical accessory for se with high-precision machine tools such as jig borers, and tool-room milling machines. Its purpose is to enable the axis of the machine to be accurately located in relation to a datum mark on the work-piece. In construction, it consists of a high-power microscope the optical path of which is bent so that the user can conveniently inspect the work from one side when the instrument is set up in the spindle of the machine. The microscope is mounted on a taper shank—No. 4 morse taper is used in the standard model but any of the usual tapers can be supplied—and the shank is inserted in the spindle. In this position the objective axis of the microscope coincides with that of the boring spindle, which the operator is thus enabled to bring within an accuracy of 0·00005 in. to the desired position.

The optical system is so arranged that the intersecting points of the graticule lines when viewed through the eye-piece, which is of the screw-focusing type, are superimposed on the point where the projected axis of the spindle falls on the work-piece. The microscope, which has a power of $\times 45$, can therefore be used (*a*) for setting the spindle over a small punch mark, (*b*) for setting the spindle over a line marked on the work-piece, or (*c*) with the aid of a reference square, for setting the spindle in the plane of any desired surface of the work-piece. The graticule or cross-lines seen in the eye-piece of the microscope are centred relative to the taper shank, but in order to compensate for a small degree of spindle run-out, should this be experienced, provision is made for the adjustment of the diaphragm to enable the cross-lines to be re-set. As the spindle is free to rotate, the instrument has the merit of being self-checking by turning it through an angle of 180°, and a rotatable reflector is arranged so that the light from any convenient lamp can be brought to bear on the job. The instrument is thus well designed to simplify what is a fundamentally difficult setting in precision machine work. The makers are Messrs. E. R. Watts and Son, Ltd., 123 Camberwell Road, London, S.E.5, from whom further details can be obtained.

Phenology of 1941

Repeating its admirable promptness of last year, the Royal Meteorological Society has issued its fifty-first annual phenological report, for the year 1941, under the editorship of Major H. C. Gunther, although it is somewhat abridged from its pre-war size. It is interesting because of the late spring and the amends of a belated summer, with a remarkably green autumn countryside and an unusually late defoliation of trees, although autumn colours were not much in evidence. The migrant birds arrived punctually in the south but late in the north; there were average numbers of the immigrant painted lady and red admiral butterflies and of the silver Y moth, while clouded yellow butterflies were reported from many parts of the country, including the north. Observations on the magpie moth and the meadow brown butterfly in relation to the rise in temperature for the June-July warm spell which followed the cold late spring illustrated how quickly certain insects may respond to the influence of a favourable spell following adverse conditions. Observations on the dog-rose furnished clear-cut evidence of the preponderating importance of the weather of the moment as compared with any latent tendencies due to a previous season, for in 1941 the flowering dates for the south-east were not less than 16 days later than those for 1940, when the south-east dates were slightly earlier than the dates for the north-west. But in 1941 the north-west dates of this flower were slightly earlier than the south-east dates. Despite the War, reports were sent in from 277 phenological observers in the scheme—only twelve less than the previous year.

Tuberculosis in Ecuador

In a recent article (*Bol. Of. San. Panamericana*, 21, 128; 1942), Dr. Jorge Higgins, director of the Anti-tuberculous Dispensary of Guayaquil, Ecuador, states that of Ecuador's three geographical regions, the coast, which has an average temperature of 81° F., is the most severely affected by tuberculosis. The port of Guayaquil, which has a population of 200,000, has the highest tuberculosis mortality in the world. The anti-tuberculosis campaign began in 1934, when the first dispensary in Guayaquil was established. A similar dispensary was afterwards opened in Quito, and more are being planned for the rest of Ecuador. During 1939, the Guayaquil dispensary provided 2,609 medical consultations, 2,406 fluoroscopic examinations, 683 pleural insufflations and 1,431 laboratory examinations; 1,169 patients were admitted and 1,831 home visits were made. A large sanatorium has been started in Guayaquil supported by a new organization called the Liga Antituberculosa Ecuadoria. Poverty, which is one of the most important factors in the causation of tuberculosis, is being partially offset by the introduction in several cities of popular restaurants where good food is supplied at popular prices. Milk stations are also furnishing milk free to the infants of poor families. Several hundred dwellings have been destroyed and their place taken by many hygienic houses for workers.

Historical Medicine and Science

Schuman's, of 30 East 70th Street, New York, have sent us their latest catalogue entitled "Medical Miscellany, List 'D'," containing an annotated list of rare books and first editions of works on historical medicine and science. In a special section on war medicine are listed the "Opera omnia medica et chirurgica" of Botallo (1660), James Handley's "Colloquia Chirurgica" (1705), Thomas Trotter's "Observations on the Scurvy" (1792), George Guthrie's treatise on "Gun-shot wounds" (1815), and William Braisted's "Report on the Japanese and Russian Medical Organization in the Russo-Japanese War" (1906) among many others. Mention may also be made of Pico della Mirandola's "Opera Omnia" (1506), the third Latin translation of Rhazes' works (1510), Thomas Willis's "De anima brutorum" (1672), Astruc's "De morbis venereis" (1740), David Brewster's "Treatise on the Kaleidoscope" (1819), Johannes Mueller's "Handbuch der Physiologie des Menschen" (1835–40), Cockayne's "Leechdoms, Wortconning and Starcraft of Early England" (1864–66), Allbutt's work on "The Use of the Ophthalmoscope" (1817), and Haeser's "Lehrbuch der Geschichte der Medicin" (1875–82).

Admiral Dumont d'Urville (1790-1842)

By a terrible railway accident at Versailles on May 8, 1842, France lost one of her most eminent scientific explorers, Admiral Jules-Sébastien-César Dumont d'Urville, whose voyages not only added much to geographical knowledge but also enriched immensely the natural history collections of the Paris museums. Born in Normandy on May 23, 1790, d'Urville entered the Navy at the age of eighteen, and two years later in the *Chevrette* visited the Black Sea. In the Isle of Milo his attention was turned to the famous statue of Venus, which was afterwards bought by the French Ambassador to Constantinople and now stands in the Louvre. In 1822 d'Urville was appointed to the *Coquille*, commanded by Duperrey, and in the course of a voyage in Oceania he made a collection of three thousand plants and another of twelve hundred insects. Returning home in 1825, he was appointed to the command of the ship, which was then renamed the *Astrolabe*. Leaving Toulon on April 25, 1826, the ship visited Australia, New Zealand, New Caledonia, New Guinea, the Carolines and other islands in the Pacific. The ship finally reached France again on March 25, 1829. D'Urville's last voyage, made during 1837-40 in the *Astrolabe*, accompanied this time by the *Zélée*, took him to the Antarctic. It was while he was engaged in writing the account o this voyage that he met his death. The train he was in caught fire, and the carriage doors being locked some fifty-two persons, including d'Urville's wife and son, were burnt to death.

Photography in Science, Medicine and Industry

The Association of Scientific Workers is organizin an exhibition which, it is hoped, will be held i November at the premises of the Royal Photographi Society. The exhibition is to illustrate the applications of photography to science, medicine and industry with the view of making such information mor generally available and better known to the public The Photographic Committee of the Association anxious to obtain examples of such work from a wide a variety of sources as possible, appeals to thos who may be able to provide exhibits to write to th Honorary Secretary, Photographic Exhibition Committee, Association of Scientific Workers, 73 Hig Holborn, London, W.C.1, for further details.

Announcements

Dr. Helen Bancroft (Mrs. Simmons), known fo her work, especially at the Imperial Forestry Institute, on the anatomy of recent and fossil plants floral anatomy and systematic botany, is interne with her husband, at Vittel. She would be ver glad to receive letters from her scientific friend during her isolation from scientific life. Her addres is: Mrs. Helen Holme Simmons, Frontstalag 19 No. 111 Grand Hôtel, Vittel (Vosges), France.

The Association of Scientific Workers has forme a committee to help in solving the special problem with which foreign men of science in Great Britai are confronted in assisting in the war effort. Foreig scientific workers interested in the work of th committee should write to the Secretary, Foreig Scientists Committee, Association of Scientif Workers, Hanover House, 73 High Holborn, W.C.

Erratum: In the communication from Dr. J. Monteverde which appeared in Nature of April 2 p. 472, the antigenic formula of *Salmonella bonariensi* through an oversight, lacks the symbol for phase of the flagellar antigen. The complete formula $VI_1 . VIII$; $i \longleftrightarrow e, n$. . . . (phase 2 is still und examination).

Effect of Shredding and Grating on the Vitamin C Content of Raw Vegetables

It is now known that a rapid loss of vitamin C takes place when the cells of vegetables are mechanically broken. During the analysis of vegetables for vitamin C, for example, it is important that all grinding or other subdivision of tissues should be carried out in the presence of metaphosphoric acid so that vitamin C-oxidase shall be inhibited before it has any opportunity of coming into action.

The loss of vitamin C which occurs in cooking has led to widespread recommendations that shredded or grated raw vegetables be eaten in the form of salads. Since the preparation thus of raw vegetables must lead to the disruption of a proportion of the plant cells, it was thought of interest to carry out the following experiments to investigate the extent of any destruction of vitamin C.

1. *Savoy Cabbage.*

Savoy cabbage from which the coarse outer leaves had been removed was cut into quarters and the four parts treated in one of the following ways:

(*a*) Grated with a household grater as commonly used for cheese or bread crumbs. The leaf was considerably bruised and some discoloration occurred.

(*b*) Shredded with a household shredder as used for suet. Some bruising was observed but not as much as in (*a*).

(*c*) Shredded with a sharp knife. No bruising or discoloration occurred.

Vitamin C determinations were carried out by the usual method of titration with 2.6 dichlorophenol indophenol on the lots of cabbage after 5, 10, 20, 30 minutes and 1, 2 and 3 hours standing in the laboratory. Replicates of the uncut quarter were analysed to determine the original vitamin C value.

STABILITY OF VITAMIN C IN GRATED AND SHREDDED RAW SAVOY CABBAGE.
(*Vitamin C mgm. per 100 gm.*)

Time	*a*	*b*	*c*
0 min.	50	50	50
5 ,,	34	48	48
10 ,,	34	44	48
20 ,,	31	44	50
30 ,,	34	46	48
1 hour	34	44	50
2 ,,	34	46	52
3 ,,	31	44	48

The results shown in the table above are in harmony with theoretical considerations. In *a*, an appreciable proportion of cells was destroyed and rapid loss of 4 per cent of the vitamin C occurred within five minutes. After this period there was no further loss. Less severe treatment *b* caused a similar loss of 0 per cent of the vitamin C. Process *c*, shredding with a knife, produced no significant destruction of vitamin.

Swedes

The previous experiment on savoy cabbage was repeated with swede. The same methods of shredding nd grating were used.

Although similar in principle to the results for abbage, the figures for swedes showed two differences. When grated, swedes lost a higher proportion of vitamin C than cabbage. The loss after three hours was 75 per cent compared with 34 per cent. After coarse shredding the losses were 39 per cent compared with 10 per cent. The more striking difference between cabbage and swede, however, was that while loss of vitamin C in the former was almost instantaneous, in the latter slow, continuous destruction occurred. With swede, as with cabbage, however, shredding or dicing with a sharp knife did not damage sufficient cells materially to affect the vitamin C content of the foodstuff.

April 16.

Natural Breeding Sites of *Drosophila obscura*

MOST of the studies on the genetic structure of wild populations of Drosophila have been on animals trapped by means of a yeasted banana-agar or similar fruit traps[1,2,3]. The flies may thus have been drawn from a large number of small discrete breeding units, and hence general inferences are difficult. I have found a very marked deficiency in the number of males trapped in *D. subobscura* Collin and to a lesser extent in *D. obscura*, although the sex-ratio in cultures approximates unity, thus demonstrating the inadequacy of collections by means of baited traps.

For many years I had attempted to secure natural populations breeding *in situ* but with no success until the summer of 1939. In that year Mr. Klaus Rothfels, at my suggestion, examined trees for exudates and found large colonies of Drosophila feeding on the yeast growths of elm tree exudates. The two most common species were *D. subobscura* Collin and *D. obscura*. This discovery was remarkable for the additional fact that a high percentage of the *D. obscura* on the site were mutants of several forms, in very marked contrast both to the proportion of mutants of the same species trapped at some distance and to the proportion of mutants in *D. subobscura* on the site. We concluded that the site was a natural breeding site for *D. obscura* but that the other species merely fed there.

Mr. Rothfels and I were to have continued the work in the summer of 1940 but this was impossible due to his sudden departure. In the late summer of 1941 Mr. Forbes W. Robertson took the matter up again. He examined a large number of trees, beech, sycamore and elm with a few oak and ash, and found yeast patches only on six elms. These were all unhealthy trees from among a group of about two hundred elms within a radius of half a mile in a moist river valley. Three of the trees were definitely moribund. The Drosophila species feeding on the yeasts were *D. obscura*, a few *D. subobscura* and occasional *D. funebris*.

The exudate and bark from one tree were removed to the laboratory for examination. Among a varied fauna we found a number of Drosophila eggs and larvæ on the inner side of the bark. These were grown in the normal Drosophila culture medium, and from 150 larvæ picked off and a large number of other eggs and larvæ, 20 male and 29 female *D. obscura* emerged to the exclusion of all other Drosophila species. Hence we concluded that the patches on elm trees form a natural breeding site for *D. obscura*.

At present the culture conditions for this species present some difficulty, but these can almost certainly be overcome. When this is accomplished we shall be in a position to undertake the examination of the genetic structure of discrete populations in relation to their known ecology.

I am indebted to Dr. O. W. Richards for the information that he had once observed what appeared to be *obscura*-like forms feeding on an exudate.

CECIL GORDON.

Resistance of a Soil Nematode to Changes in Osmotic Pressure

THE results detailed below are considered to be of sufficient interest to merit early publication. An amplified account will be published in the future, when a description will be given of the species of Rhabditis which was employed. The worms were cultured in an agar broth the osmotic pressure of which was equivalent to that of about 30 m*M*. sodium chloride.

On immersing the worms in distilled water, the body swells, but the alimentary canal swells more slowly than the rest of the body. Similarly, in concentrated saline solutions, the body shrinks, the alimentary canal shrinking more slowly than the remainder. These results show that water can pass into and out of the body down a gradient of osmotic concentration, and also that the main aqueous exchanges do not occur through the gut. Further work indicated that these exchanges occur through the general body surface.

During shrinkage in concentrated solutions, vacuoles are occasionally observed between the cuticle and hypodermis. By analogy with conditions in a plasmolysed plant cell, it seems likely that the cuticle is more permeable to the substances in solution than is the hypodermis. Further experiments with cyanide solutions also suggested that the living tissues of the body wall, rather than the cuticle, are primarily responsible for controlling the permeability of the body wall.

After about fifteen minutes in distilled water, the amount of swelling of the body of the worm is reduced. This reduction is not observed with injured animals, nor when *M*/100 potassium cyanide is used instead of distilled water. These results show that there is, in distilled water, an active method of osmotic regulation whereby the size of the body is reduced. The alimentary canal probably plays some part in this regulation, since fluid is ejected from the anus during the later stages of reduction in size.

On prolonged immersion in concentrated saline solutions, the body slowly re-expands. If, towards the end of this process, the worms are transferred to distilled water, the amount of swelling which is produced is less than that obtained with animals which had not re-expanded. This suggests tha in these conditions, osmotically active materi is passing out of the body. The avenue of escap could not be decided upon with certainty.

The conclusions reached contradict the genera impression that free-living nematodes can withstan osmotic changes because they possess an impermeabl cuticle[1], and indicate rather that this resistance i due to an active method of osmotic regulation. Th conclusion that the cuticle is relatively unimportan as an insulating covering, agrees with the conclusion reached as a result of past work upon parasiti nematodes[2].

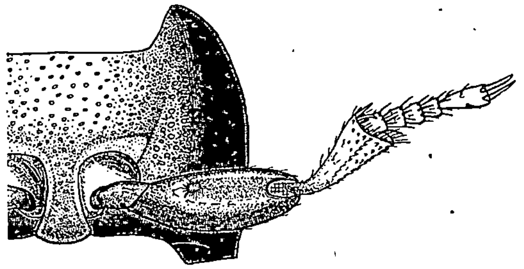
Secondary Sexual Characters of Triboliu

THE confused flour beetle, *Tribolium confusum* J du V., and the rust-red flour beetle, *T. castaneu* Herbst, are the most abundant and destructiv beetles infesting flour and other prepared cere products. *T. confusum* is also one of the insect most commonly bred in the laboratory for exper mental purposes. Hitherto it has been maintained[1,2], that there are no secondary sexual characters in th adult stage, and in consequence the beetles coul only be sexed in the pupal stage, a procedure whic is frequently very inconvenient.

I have recently found that the males of bot species have on the basal fourth of the ventral sid of each femur a shallow, oval pit from which aris numerous, erect, golden-yellow hairs. The female have neither the pit nor the associated brush hairs. In *T. castaneum* (see accompanying illustratio this pit is about 0·04 mm. broad, and the hairs a nearly as long as the breadth of the pit. In livin specimens of this species the presence or absence the pit and hairs can be detected with certainty wit a hand lens of × 15. Specimens to be sexed shoul be held with the back against the index finger an the thumb nail, which needs to be moderately lon pressed gently just behind the front legs. With little practice they can be sexed without injur Alternatively, the insect can be picked up by touchi its back with a wet brush, or, as suggested to me Dr. J. P. Harding, it can be held in a Rousselet liv box.



Tribolium castanum HERBST, MALE. VENTRAL VIEW OF LEFT FRONT LEG.

T. confusum has a similar but smaller pit (0·03 m broad) and is difficult to sex without the aid of binocular dissecting microscope under which the specimen may be held as described above. In the males of *T. confusum* the middle and hind femora also have pits though these are much smaller and more difficult to see than those of the front femora and usually contain only 2–4 hairs.

Mitosis in Amœbæ

The life-histories of four large, free-living amœbæ have been worked out here; one, namely, *Amoeba lescheri* n.sp. not yet published. But except for *Amœba dubia* (Schaeffer) in which Sr. Bernardine (Dr. L. A. Carter) discovered it in 1913, mitosis had until recently not been demonstrated. In fact we doubted its occurrence.

Pending the publication of a full account of mitosis in these amœbæ and of the whole life-cycle of *A. lescheri* (n.sp.), we should like to state here that we have now also discovered the phenomenon of typical mitosis in the binary fission of (1) *Amœba proteus* γ (= *A. proteus* (Schaeffer); (2) *Amœba discoides*; and (3) *Amœba lescheri*.

Flow of Liquids in the Critical Region

In experiments on the flow of water in a long copper tubing, it was found that the inlet pressure must be maintained free from disturbances to the highest degree possible if flow in the critical région is to be analysed. When extraneous disturbances were eliminated, the flow in the tube falling between Reynolds' numbers 1,000 and 5,000 was found to fall into three distinct classes, all of which were different from both the viscous and the turbulent regimes. Strictly speaking, only the regime existing between 2,200 and 2,500 Reynolds' numbers in the present system showed the ordinarily accepted criteria of critical flow. Nevertheless, as both the regions between 1,000 and 2,200 and between 2,500 and 5,000 fall outside the laws of either viscous or turbulent regimes, they are treated here as 'pre-critical' and 'post-critical' regimes.

In the accompanying graph, the corrected head lost per unit length of pipe is plotted against the average linear velocity of the water in the pipe, for values of Reynolds' numbers ranging between 240 and 2,800 approximately. It is seen that there are four distinct sections of the curve.

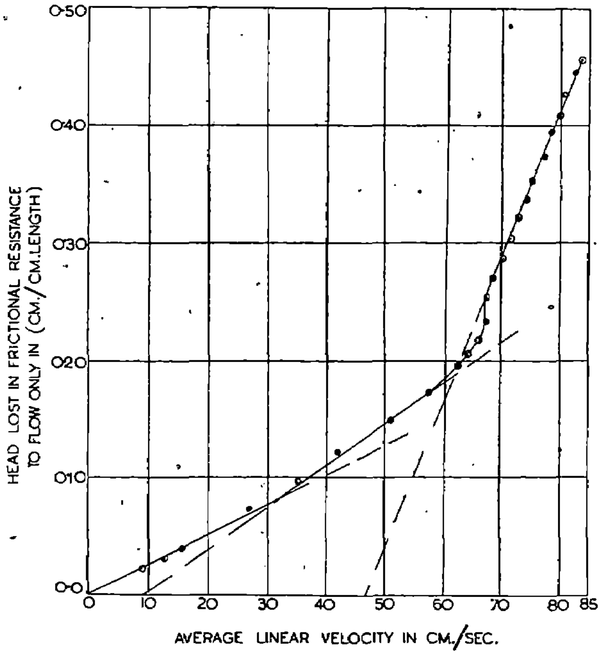
(1) Up to *circa* 1,000 Reynolds' numbers, the ordinary straight line of the viscous regime obtains, characterized by (*a*) passing through the origin, and (*b*) by its slope being governed solely by the viscosity of the fluid in so far as the properties of the fluid are concerned.

(2) Between 1,000 and 2,200 Reynolds' numbers approximately, a second straight line obtains. This straight line differs from the first in that (*a*) it does not pass through the origin; (*b*) it has a higher value for its slope than the first line.

(3) Between Reynolds' numbers of 2,200 and 2,500 approximately, the curve rises almost vertically upwards in the direction of the pressure loss. It is in this and the following region that it becomes essential to eliminate all disturbances from the entry. As mentioned above, strictly speaking this is the critical region.

(4) Between 2,500 Reynolds' numbers and about 5,000, above which the curve shows a definite curvature characteristic of the turbulent regime, there is yet another straight line. The graph goes up to 2,800 only, but other experiments showed that curvature begins above 5,000. This straight line again does not pass through the origin, and it has a steeper gradient than both the viscous and 'pre-critical' lines.

Another important point in connexion with these lines, which is not evident from the graph, is that in the critical region a change of 25 per cent in the viscosity of the flowing water appeared to have no effect on the position or slope of the lines, especially the 'post-critical' curve. Of course, the viscosity is of paramount, but indirect, importance, in that it influences the type of regime obtaining in the pipe.



Thus, it appears that the classification of flow as viscous, critical and turbulent is an over-simplified system. In unpublished work carried out in this Department and to which reference has already been made[1], it became evident that when flow is at extremely low rates, in a medium of high specific surface, such as might obtain in the flow of fluids through porous strata in oil, gas or water production, then the law of frictional resistance due to flow did not follow the laws of the viscous regime. In other words, a 'sub-viscous' or 'pre-viscous' regime of flow appears to exist. Flow then adopts the viscous regime when the velocity is increased, and as is seen here, passes through an intermediary type of flow before it enters the critical regime. Before entering the fully turbulent type of flow, it passes through still another distinct type, the post-critical regime. At extremely high Reynolds' numbers the flow becomes further complicated by the production of certain sound waves.

A final point of interest here is the possibility of using the vertical section of the graph in the production of accurately constant rates of flow in instrumental and process controls, as a very great change is required in the overall head loss to produce a small change in the rate of flow.

It is hoped to publish a fuller report than this elsewhere.

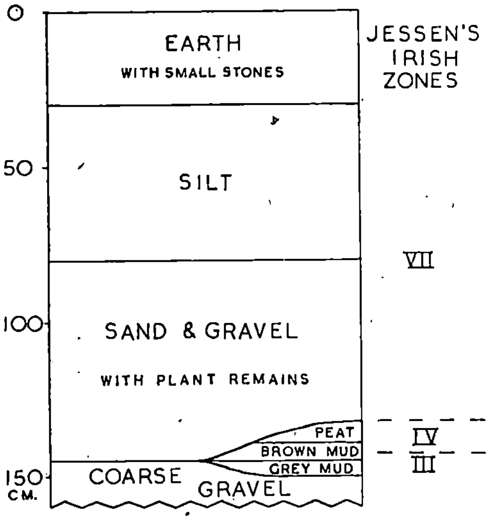
A Late-Glacial Flora in Co. Monaghan, Ireland

IN 1715 the molar teeth and other remains of a mammoth were discovered to the east of Belturbet, Co. Cavan[1]. In 1940 a site in the townland of Drumurcher, Co. Monaghan, where near a mill there was a small alluvial flat, was tentatively identified as the place of the original find.

The alluvial flat, which lay between a ridge of rock and a drumlin, was covered by a layer of earth and small stones, certainly disturbed. Under the earth was a layer of sandy silt and below this was a fine river gravel rich in plant debris, including many Corylus nuts and some tree stems. Little pollen of the pine but abundant pollen of the alder was found in the silt and the gravel. These deposits should, therefore, have been laid down after the beginning of Jessen's Irish Zone VII[2]. In places the gravel rested on a fine-grained peat rich in Salix leaves and containing also remains of Betula spp., Potamogeton spp., Carex spp., *Scirpus lacustris*, etc. Only pollen of the birch, pine and willow was found in the peat; it should, therefore, belong to Jessen's Irish Zone IV. Downwards the peat passed over into a brown mud; this in turn became grey in colour and rich in sand. The grey mud rested on a coarse river gravel without plant remains; the bottom of the gravel was not reached. In the muds, tree pollen was very scanty. In places the upper gravel lay on the muds or directly on the lower gravel. The stratigraphy, which is illustrated in the diagram, agreed with that outlined in the original description.



The grey mud was rich in plant remains, among which the following plants were noted—Arenaria spp., *Armeria vulgaris, Dryas octopetala, Oxyria digyna, Salix herbacea* and *Thalictrum alpinum. Dryas octopetala* excepted, all these plants were previously found in a solifluxion deposit at Ballybetagh, Co. Dublin[3]. With this deposit, associated with a local glaciation in the Wicklow Mountains[4], the grey mud at Drumurcher is presumably contemporaneous. The Drumurcher site is about three hundred feet above sea-level. The presence of the small-leaved arctic form of *Dryas octopetala* in Co. Monaghan supports Jessen's suggestion that these Irish late-glacial deposits may be contemporaneous with the upper Dryas clay of Denmark. Though no traces of mammoth were found in 1940, the resemblance of the flora of the grey mud to that associated with mammoth remains at Borna[5] is worth noting.

Thanks are due to Mr. J. Andrews, the tenant of the site, for his co-operation, and also to Mr. A. Farrington and Mr. A. M. Gwynn for their assistance in the field. The work was made possible by a grant from the Royal Irish Academy, in the *Proceedings* of which a full report will be later published.

Russian for Scientific Workers

THERE must be many scientific workers who would like to learn Russian if facilities were available, and there are certainly some excellent schools of Russian in Great Britain which would offer facilities. The most useful course would be one which would enable a student to read a Russian scientific paper with the aid of a dictionary and not too great an expenditure of time: on a foundation of this sort, a fuller and more general knowledge of the languag could, if circumstances permitted, be developed.

The School of Slavonic and East European Studie of the University of London is making a start with a beginners' class open to any student, and as an act of marked generosity, given without fee to persons employed by the University or its institution in teaching or administrative posts. Other course are arranged elsewhere.

The purpose of this letter is to ask whether ther are groups of scientific workers who would like t learn Russian, if the necessary arrangements coul be made. There seems little doubt that the teachin could be provided in many cases at least, and if on knew the extent of the unsatisfied demand, it wou be possible to set about meeting it. I should welcom any suggestions or comments.

X-RAY ANALYSIS IN INDUSTRY.

X-RAY analysis provides a new tool for solving industrial problems. It is used in many laboratories in Great Britain, and the researchers who have become expert in handling it are constantly developing new methods, and discovering new types of problem to which it can be successfully applied. The Conference arranged by the Institute of Physics, and held at Cambridge on April 10 and 11, had as its object the interchange of ideas and knowledge between the various groups of workers. Two previous attempts to call this Conference have been frustrated, the first by the onset of war and the second by the difficult conditions of the summer of 1940. In order that the object which it had in view might at any rate be partially achieved, the Institute of Physics decided to publish the series of papers which appeared in the *Journal of Scientific Instruments* in May and July 1941; these papers formed the basis of discussions for the present Conference. Some anxiety was felt by those responsible for the arrangements, lest preoccupation with war-work would prevent many from attending, but the decision to proceed was made because the X-ray tool is being widely used for problems directly connected with the War. The large attendance at the Conference (some 280 participated) and the generally expressed appreciation of this opportunity for discussion have shown that this anxiety was unnecessary.

X-ray analysis found its earliest application in the study of crystalline structure, the pattern of the atomic arrangement in the perfect crystal. The results of this analysis have had a profound influence on fundamental concepts of the nature of chemical combination. It has been realized that the law of combining proportions is not always the result of the grouping of atoms into molecules; in many classes of compound it represents the ratio of the numbers of atoms which are welded by the interatomic forces into one continuous pattern. It has been realized that one must be cautious in carrying over into the metallic field concepts based on organic and inorganic compounds, and the physical realities behind such terms as 'intermetallic compound', 'phase', and 'solid solution' have become much clearer. Such work ultimately influences technical applications, because it clarifies ideas.

The Conference concerned itself, however, with more direct applications of the X-ray method, and the subject of crystal analysis was specifically excluded, or rather, its results were taken for granted. An actual crystalline material may be composed of fragments with different types of crystalline structure. The crystallites have characteristics of size, of shape, of orientation, and of perfection, which may profoundly modify the macroscopic properties of the material. The perfect pattern is an ideal only attained by crystals under special conditions. In 'mixed crystals' various atoms may serve as proxies for each other, and an increasing number of crystals are proving to be tolerant to a remarkable extent of minor variations in their pattern without destroying its general plan. X-ray analysis affords valuable information about their characteristics, and is often the only available method of attack; the study of such problems was the business of the Conference.

The progress of an X-ray analysis is reminiscent of that in a good detective story. It is an indirect method. We cannot extort a full confession from the guilty party. Instead, we are given a series of clues, which point to some possibilities and exclude others, until finally we have an accumulated weight of evidence which makes us confident we have arrived at the right solution. The indirect nature of the evidence is seen most clearly in the analysis of crystalline patterns. Theoretically, the observed X-ray diffraction effects might be produced by an infinity of arrangements of scattering matter (in technical terms the phases of the scattered beams are not observable). A unique solution is only possible because other evidence can be called in support. The right solution must represent atoms of known number and type, with features of arrangement and spacing relative to each other which previous experience with other structures has shown to be characteristic. Instead of logically deducing a solution, intelligent guesses have to be made and tested against the observations. The same is true for X-ray analysis of all types. The clues afforded by the more or less diffuse spots, arcs, or lines on an X-ray photograph of some mysterious material must be combined with a wealth of other knowledge if they are to be followed up. Much of the fascination of X-ray analysis is due to its taking one into so many other fields of science. The X-ray expert should not only understand the optical principles on which his science is founded; he must at the same time be a chemist, a metallurgist, a petrologist, or a biochemist. The optical principles can be logically deduced, but imagination, common-sense and a wide general knowledge lead him to make his intelligent guesses.

The wide range covered by the industrial applications is shown by the papers published last year. In the short time available at the Conference detailed discussion of all the papers was not practicable, and it was decided to group certain of the papers together and discuss them under the three headings: "Cameras for X-ray Analysis"; "The Application of X-ray Crystallography to Industrial Problems"; "X-ray Structure and Mechanical Properties". At the same time an exhibition of photographs, films and apparatus cognate to the above subjects was arranged. This exhibition was well supported, and examples of recent work and modern apparatus emphasized the very marked improvements in technique which have taken place in the last decade.

The papers, and the contributors to the discussion at the Conference itself, all came from laboratories in Great Britain. They did not represent a general review of the application of X-ray analysis to industrial problems, which has been advanced by workers in many countries. The limitation was deliberate. The Conference was planned to be a comparing of notes and pooling of knowledge by the many X-ray workers in Great Britain who desire to collaborate more closely, and it has done much to further this aim.

In each discussion the procedure adopted was that the main aspects of the subject were introduced by speakers who had contributed papers to the symposium, and afterwards a general discussion took place. This present account of the proceedings deals only with the more interesting items arising from the general discussions.

On cameras, two interesting developments may be mentioned, one by Orowan of the Cavendish Laboratory, Cambridge, describing the use of a rotating wire grid which enables much extra useful information to be obtained from rotating crystal photographs, and the other by Frommer of High Duty Alloys, Slough, concerning the design of very large cameras in which completed metallurgical products can be examined for measurement of internal stress.

The discussion on applications brought out the very great diversity of subjects now being investigated by X-ray methods. Bunn of Imperial Chemical Industries, Ltd. (Northwich), in his remarks emphasized the need for the production of an index of the known structures of chemical compounds, etc., as this would be a great help in the identification of compounds. This question was the subject of further comment by other speakers, and was referred to the organizing committee of the Conference with the view of promoting active steps to provide an index for X-ray workers.

The final discussion was concerned with the correlation of X-ray structure of metals and mechanical properties. Numerous speakers indicated how industry is developing this subject in connexion with such problems as the measurement of internal stresses and preferred orientation in strip and wire, and on the theoretical side Sir Lawrence Bragg showed how the measurements by Wood on the limiting crystallite size of metals can be used to estimate in a simple way their yield strength within very reasonable limits.

On April 10, Sir Lawrence Bragg delivered a lecture entitled "The History and Development of X-ray Analysis." This was a very enjoyable feature. It commenced with a fascinating account of the early work of himself and his father, the late Sir William Bragg, and after tracing the major developments up to the present time, ended with a statement of various problems, such as the structure of proteins, the 'fine' structure of deformed metal, etc., which were in his opinion on the threshold of solution.

As a result of the interest displayed at the Conference and the enthusiasm of the members, a resolution was passed suggesting that the organizing committee should take steps to set up a permanent organization under the ægis of the Institute of Physics to arrange similar conferences from time to time.

CRYSTALLINITY IN CELLULOSE ESTERS

According to an article by W. O. Baker (*Bell Lab. Rec.*, 20, No. 6, Feb., 1942) the toughness, strength and flexibility of plastics are influenced by the arrangement as well as the composition of their giant molecules. In an endeavour to discover the fundamental properties of certain compounds such as cellulose acetate and cellulose butyrate, which make these materials resistant to shock, bending, twisting and dimensional change, studies were undertaken on a molecular scale, the high magnification necessary being obtained by photographing X-ray beams after passage through selected samples of the plastics. These photographs give patterns which can be measured to show molecular distances as small as a billionth of an inch; and they also indicate how the molecules are placed with respect to each other.

A minute cylindrical beam is passed through small flat sections about one millimetre thick, much of it expanding into coaxial cones on account of diffraction by the layers of molecules. After an exposure of three or four hours, circular records appear on the photographic film, the degree of crystallinity being indicated by the sharpness and number of circles recorded. In striking analogy to metals, it was found that the cellulose esters could be quenched by rapid cooling from the molten state. The long polymer molecules were then found to be disordered with respect to each other. Neighbours of a given molecule are quite randomly arranged although there is a tendency for sections of the chains to lie side by side. When cooled slowly, however, the molecules have a very ordered arrangement in local regions throughout the plastic. When they have the maximum disorder, the material tends to be most soft and flexible, and when they are most ordered, or crystallized, it is hardest and strongest, but sometimes brittle.

Two other methods of controlling the number of organized and disorganized molecules have long been used as working procedures in the technology of cellulose plastics. The first is to control the shape of the cellulose ester molecules by the amount of the reaction and the nature of the substituting groups so that they can only partially fit together, to give an ordered arrangement. The second, applying chiefly to lacquers such as aeroplane dopes and film formation, is the selection of a particular solvent which evaporates as the cellulose ester film dries. Various liquids were found to cause different amounts of molecular disorder in the resulting films.

The study showed that sections of the plastic's molecules could orient themselves in an ordered position in the solid state and that they undergo considerable torsional motion under the influence of temperature. Thus, it was possible to anneal quenched cellulose esters, and X-ray patterns show how this process causes the chain molecules to take up ordered positions. This ability of molecules to move in plastic solids even at ordinary temperatures appears to be closely related to their plasticity and capacity to bend and return to original form.

DEVELOPMENTS IN ADULT EDUCATION*

By DR. BASIL A. YEAXLEE

University of Oxford

Despite all that has been done in the field of educational psychology adult education has still only an empirical basis. There has been practically no research in Great Britain and very little in the United States. Yet without such careful inquiry it is not possible to plan effectively the great extension of the movement that is desirable after the War or to develop the necessary variety of methods. The first stage is to determine the problems to which the attention of psychological investigators should be directed. The educational activities now so widespread among men and women of H.M. Forces should yield valuable data and suggestions.

It must be remembered that nothing like simple extension into this constituency of work on conventional lines was feasible. The opportunity was, and is, immense. But conditions as a rule prevent the systematic, continuous study and the maintenance of academic standards which characterize the courses and classes carried on among civilians in peace-time by university extra-mural departments and organizations such as the Workers' Educational Association. On the other hand, a very small percentage of the population is normally reached by these activities, and a great deal of genuine adult education has been and always must be unorganized. The Central Advisory Council for Adult Education in H.M. Forces, however, which through its twenty-three regional committees makes the civilian resources of the country in lecturers and teachers available to the Services, now reports not only a constantly growing number of single lectures but also a gratifying increase in the demand for short courses*. An extract from one lecturer's diary runs: "The course which never ends: now on Course III, Lecture 8—or something like that: gave a talk on three famous Concertos, the Tchaikovsky, Grieg, and Addinsell's Warsaw Concerto." Another lecturer's report refers to the "widespread evidence of a new sensitiveness to political and economic issues on the part of the average soldier". This lecturer also says: "The mood is sometimes cynical, but more often it is shrewd, positive and percipient, quick to question glib assumptions and assurances, unafraid to seize upon often disconcerting comparisons, but eager to be informed, convinced and reassured on the grave questions that abide the issue of their day."

---

* Substance of an address to the Education Section of the Britis Psychological Society at its Extended General Meeting, Brighton April 10, 1942.

Adult education among members of the Forces, as among civilians, relies upon the interest of the student. There is no prescribed curriculum, as in schools and universities. Attendance is voluntary, if it is in leisure time, as this work is intended to be. Facilities are open to all. It has been said, however, that of course only some 20 per cent of the troops are in the least likely to avail themselves of these, since that proportion can be safely taken as the maximum number of people who show any interest in adult educational activities, whether cultural or vocational, in civil life. If this proves even approximately true, however, it reflects more upon what is offered than upon those who ignore or reject it. We cannot be content to believe that 80 per cent of men and women are completely devoid of cultural interests because they are unattracted by lectures and discussions on topics which appeal to he 'intelligentsia'. The question for the psychologist s whether adult education has not been too much limited to intellectual interests. He must indeed ask also whether school and college education has been o intellectualist or so utilitarian that average people misunderstand the very word education and do not dream of connecting it with the word adult, or with life as they have to live it.

The rapidly extending practice of arts and crafts y men and women in the Services is one of the actors in the present great experiment that may be f greatest importance in the future development of adult education. It has been said by some that music, drawing and painting and recreative handicrafts have no place in a war-time scheme of adult education because, in their view, these have no rela-on to the serious business of understanding either he causes and issues of the world conflict which now emands the exercise of all our mental and physical nergies or the aims and conditions of social and olitical reconstruction when victory has been won. he majority, however, would not agree. For in uch occupations men and women are neither escapist nor inclined to fiddle while Rome is burning. They are discovering that they have creative imagination and constructive capacity. The importance of this not only educationally and psychologically but also sociologically is all the greater at a time when thousands of men and women are making closer acquaintance than ever before with what mechanization means. It is on this side much more than on the more academic that they are finding new interests, and achieving that greater completeness and balance of personal development which are so greatly needed if human society is not only to recover from the cataclysm of war, but also to approximate more nearly to the good life.

Educational activities among the women's Services are not so extensive as among the men. This is partly due to the fact that hitherto they have not had their own education officers and organization. That deficiency is being remedied. The Director of Army Education now has an A.T.S. officer with the necessary training and experience attached to his staff at the War Office, and soon there will be a similar appointment in each Command. Action has also been taken by the W.R.N.S. and W.A.A.F. Directorates. It is important to note this because the expansion of the Army Educational Corps at once produced a much greater volume of educational demand and experiment among the men, and doubtless the same will happen in the case of the women. But in all probability the women's needs and desires, understood by their own education officers as even the most sympathetic of men cannot be expected to understand them, will not be merely for 'domestic' subjects and 'feminine' activities. They will want many of the same things but will approach them from a different aspect. What the educational psychologist should be finding out is how far it is true that, contrary to popular notions, women are the more practical in their thinking and men the more abstract and theoretical. The two, of course, are complementary. Men and women in the Services share educational activities to an increasing extent. But when women are drawn in much greater numbers into participation in the scheme, many will want programmes of their own. It would be a great pity and a serious loss if now and after the War 'women's interests' in adult education were misconceived, and if attempts to make special provision for them failed correspondingly.

It has been found that women are more inclined than men to seek pure relaxation in their off-duty hours, especially in the evening when the day's work is done. This raises another psychological question —the nature and reciprocal effect of physical and mental fatigue. That men and women work equally hard there is no doubt. But it is probable that a far larger proportion of women than of men are engaged on monotonous duties very similar to some aspect of their peace-time employment. For the greater number of men, joining one of the Services means learning how to do a considerable variety of things which are new to them and several of which usually come into the same day's work. Physically, women often have more endurance than men, though less brawn and muscle. The fatigue they exhibit—or at least the inclination to seek amusement rather than education after a hard day's work—may well be due to monotony rather than to physical exhaustion and may well be more mental than physical. A study of this would be of value in considering what forms of adult education should be promoted when peace-time conditions of work and leisure are restored. In this connexion again it is worth while to remember what great use the U.S.S.R. has made in adult education of the arts—films, music, the theatre, opera and so forth—as well as of physical training and open-air sports.

---

*The figures for the six months April 1–Sept. 31, 1941, which will greatly exceeded by those for the ensuing winter half-year, are ,983 single lectures, 1,530 short courses, and 1,075 classes arranged rough the agency of regional committees. These do not include al education authority classes or lectures and classes arranged ernally by the Services themselves, using their own personnel. CA is of course an independent activity, all talks being given and cussions conducted by regimental officers in parade times.

There are two tensions to be maintained in adult education. One is between amusement and educational seriousness. Adult education must be recreative and at the same time must not lose real educational content and quality. The other is between emotional states and intellectual effort. There is always a tendency, as war goes on, to take more and more the attitude *delenda est Carthago*, but this results more from a cumulative feeling than from reasoned judgment. World reconstruction will demand discrimination of a kind incompatible with hatred. There has been a considerable degree of spontaneous refusal to accept Vansittartism, but all the time there is a tendency to drift into precisely that state of rationalized hatred and aggressiveness. Similarly the increase of propaganda, of however legitimate and truth-telling a kind, begets a tendency to scepticism and a temper of suspicion. Thus, for example, the unvarnished account by a German refugee of his experiences in an internment camp was received with incredulity by men who assumed that it was rather a blatant attempt to whip up their 'morale'. Years ago, Mr. Walter Lippman warned us of the universal tendency to judge everything by "the picture in the mind". If the problems of democracy and of a planned society after the War are to be solved happily and with reasonable speed, adult education, now and then, must both evoke and sustain the power of imagination and equally train the critical judgment.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk is open to the public*)

Wednesday, May 6

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Prof. J. C. Drummond: "War-Time Nutrition and its Lessons for the Future".

INSTITUTION OF ELECTRICAL ENGINEERS (WIRELESS SECTION) (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Discussion on "Post-War Planning in Radio Communication" (to be opened by Colonel Sir A. Stanley Angwin and Mr. H. Bishop).

Thursday, May 7

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Annual General Meeting. 6.30 p.m.—Adjourned Discussion on "A Critical Review of Education and Training for Engineers", by the Education and Training and Personnel Sub-Committee.

Friday, May 8

ROYAL INSTITUTION OF GREAT BRITAIN (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. James Kendall, F.R.S.: "The Separation of Isotopes and Thermal Diffusion".*

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

HORTICULTURAL DISTRICT OFFICER in South-East Norfolk—The Secretary, Norfolk War Agricultural Executive Committee, Sprowston, Norwich (May 8).

UNIVERSITY CHAIR OF OIL ENGINEERING AND REFINING (PETROLEUM TECHNOLOGY)—The Secretary, The University, Edmund Street, Birmingham 3 (May 9).

UNIVERSITY READERSHIP IN ORGANIC CHEMISTRY tenable at London (R.F.H.) School of Medicine for Women—The Academic Registrar, University of London, Richmond, Surrey (May 12).

LECTURER IN MECHANICAL ENGINEERING SUBJECTS—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham (May 16).

ORGANIZATION OF PRODUCTION

THE interest with which the recent debate in the House of Commons on production was followed indicates how thoroughly the importance of the issues is understood in Great Britain, and the anxiety that there shall be no further weakness in either administration or in policy. The limitations of man- and woman-power, and also of materials, are much too severe for there to be complacency over waste either through individual slackness at the level of the operatives or through inefficiency at that of management. The speech made by Mr. Oliver Lyttelton as Minister of Production was clear and encouraging. He has an exact notion of what is to be accomplished, and he made the new arrangements sound more reasonable than they did in the Prime Minister's formal announcement.

The Minister of Production faces three major tasks. One is to ensure that the domestic production programme of Great Britain is both balanced and efficient. The second is to integrate it with the programmes and needs of the other united nations, and particularly with those of the United States. The third is to ensure "a complete fusion between military plans and thought and production plans and thought", not only in the realm of strategy, but also in that of battle tactics. It is this task, probably the most urgent, that has for some time been the special concern of scientific workers. It has been the burden of conferences arranged by the Association of Scientific Workers on science and the war effort. It was voiced by Sir Henry Tizard at the annual luncheon of the Parliamentary and Scientific Committee, and it was the main theme of Prof. A. V. Hill's long speech in the House of Commons on the war situation on February 24.

Mr. Lyttelton's statement that to accomplish this purpose there is to be what he described as a general staff of war production goes some way to meet Prof. Hill's plea for a general staff with executive functions, including a full-time technical section of able officers of all arms who have grown up with modern weapons and equipment, to deal with the general strategy of the War. The body described by Mr. Lyttelton is designed to be an exact parallel to the Chiefs of Staff Committee on the military side. It will consist of his Chief Adviser on Programmes and Planning, Sir Walter Layton, the assistant chiefs of staff of the three Services, together with the highest technical officers of the three Production Ministries, and will be the servant on war production matters of the Defence Committee.

The Joint War Production staff will be served by a Joint War Production Planning Group concerned with the planning of what is to be produced, and composed of Navy, Army and Air Force officers and representatives of the Production Ministries working together in the same office. These proposals forestall some of the recommendations in the Eighth Report of the Select Committee on National Expenditure, dealing with the organization of production, which has since appeared, particularly those relating to a balanced plan, to an adequately staffed

Intelligence and Programmes Branch, and to the examination as a matter of urgency of means of formulating with precision, and so far as possible in advance, the demands of the Fighting Services. The Joint War Production Staff with the Programmes and Planning Division will work in close touch with, and supply information required by, the combined Anglo-American organization. Arrangements are being made to include a study of the war production and requirements of the Empire, and Mr. Lyttelton was at pains to stress that the object of the new organization is to ensure that production is closely and continuously related to strategical requirements as well as battle tactics.

This section will be in the charge of Sir Walter Layton, and will also be intimately concerned with such combined problems facing the United Nations as the dovetailing of the British supply of raw materials and British manufacture of munitions into the programme of the United States. A special Raw Materials Division will deal with general policy on the development of raw materials, on the control of import of raw materials, the allocation and releases of stocks of raw materials, with an Empire clearing-house and with the relations between the British Raw Materials Committee and the committee in the United States which deals with the combined raw material requirements and supplies of the United Nations. A further Production Division will be a small technical division in the charge of an industrialist with wide general experience. To him will be attached a technical officer from each of the three Production Departments, so that the closest touch will exist between the Production Division and the Department. The main functions in the industrial field of this Division will be those subjects which affect all three Production Departments simultaneously.

Mr. Lyttelton will address himself particularly to the problems of steady production in the face of changes in the enemy's strategy, in the geographical theatres of war, the accession of new allies, the appearance of new enemies, and the interruption of sources of raw materials, which may oblige us to substitute one type of munition for another. Moreover, he recognizes the importance of relieving the natural concern and anxiety of workers who may find idle time on their hands from such causes. The new Minister of Production is clearly resolved to see that enforced idleness, whether it springs from the loss of shipping carrying essential supplies, the necessity of substituting a new type on a sudden message from the battle-front, or delay or destruction due to enemy air attack on factories or communications, does not become the breeding-ground of suspicion and misgiving.

The importance of taking the workers into the Government's confidence in this respect, in order to achieve the extra production and with it the aggressive spirit in industry as well as in the Fighting Services, is not easily overstressed. It will go far to eliminate the bad discipline which is another source of inefficiency, and in itself it should be a spur to more efficient management where required. Mr. Lyttelton promised that no defects will be glossed over, and that where something is proved to have been wrong, such measures as are possible will be taken to put it right.

Mr. Lyttelton said little himself about management efficiency, but the whole tone of his speech implies that he is prepared to countenance disciplinary action against management as well as against worker where required. There is already the precedent of the War Agricultural Committees in dealing with inefficient farmers, and if similar measures were applied to the managements of workshops or factories where required, and in backward establishments there were enforced those simple rules upon which the health and efficiency of labour so largely depend, much would have been done to remove suspicion of unfairness and to create the conditions for effective team-work upon which so much depends. The new Regional Division, the most radical change announced by Mr. Lyttelton, is an attempt to raise the standard of organization of production among the many smaller firms, and like the works committees, will depend for its success largely upon such a spirit of co-operation. Local organizing ability will be given a chance to show itself, just as the works committee can be used as a clearing-house for explanations and suggestions and for levelling up practice in all the shops of one trade.

But team-work must be forthcoming from more than the workers and the factory management. Mr. Greenwood's observation that in the past there has not been the full team-work and co-operative spirit in the Production Departments without which maximum effort is not possible should be taken to heart at the very top as well as at the bottom. In this connexion the Seventh Report of the Select Committee on National Expenditure, which has since appeared, points out that so far the organization o labour supply has not been undertaken with tha breadth of conception and firmness of execution whic are necessary for the creation of our maximum militar strength. The Minister of Production's spirit o co-operation and open mind must be widely shared i we are to solve all the difficult strategic problems o production and of man- and woman-power, perhap especially those involved in the increasing use o women in industry and the exploration of the use o part-time labour.

Mr. Lyttelton's clear conception of the power attaching to his office—his supreme authority ove raw materials and over machine tools, and a co ordinate authority over labour—and the machiner which he has superimposed on that already existin interlocking the affairs of the workers with those the fighters, have already engendered high hopes the instrument in his hand. Whether he is to wie it effectively for the destruction of the enemy depen on more than Mr. Lyttelton's own personality an ability. It depends on the support and co-operatio which he receives from the Cabinet downwards, an the more boldly he uses his authority the mo loyally he will be supported.

Organization alone will not secure the full pr duction that is desired, though that is no reason f tolerating inefficient administration, bad management or defective organization. The shortage of efficient administration makes it essential, as Sir John Wardlaw-Milne insisted, to use the large number of men of fifty and above who have wide administrative experience but are largely unused. But to knit Government, management and workers into one harmonious team keyed up to its maximum effort and efficiency, we need a new spirit of aggressiveness.

There may be differences of opinion as to whether that new spirit will spring, at least directly, from the self-interest which Sir John Wardlaw-Milne stressed in this connexion. There is likely to be wider support for Sir William Beveridge's view in his plea for a new spirit in grappling with total war, that if war is to be waged offensively against evil, for the ideals of tolerance, fair play, freedom of thought and speech, kindliness and the value of the individual soul, it must be in the spirit and passion of a crusade, in a spirit of service, transcending the thought of duty alone.

There are few scientific workers who would not respond to Sir William Beveridge's noble plea in his recent article in *The Times* for the casting aside in this time, and for the building of the peace when victory is won, of the obsolete party allegiances and ideals, of profit and of selfish and money-making motives. These are the obstacles to full comradeship and trust, in production as in arms, and Lord Hankey's weighty words on the machinery of government in the House of Lords point to a weakness in government, to which Sir William Beveridge also referred, through the attempt to construct the Government more on the balancing of party considerations than on grounds of national efficiency. Service rather than gain should be the main motive of war effort in Government and in industry as in fighting. There can be no doubt of the response of the nation to great leadership; it is earnestly to be hoped that the new production machinery will be boldly and imaginatively used, that constructive ideas will come from above, and that inspired leadership will kindle a new comradeship and loyalty which shall carry us swiftly to full victory.

MODERN THEORY OF CHEMICAL REACTIONS

The Theory of Rate Processes

The Kinetics of Chemical Reactions, Viscosity, Diffusion and Electrochemical Phenomena. By Samuel Glasstone, Keith J. Laidler and Henry Eyring. (International Chemical Series.) Pp. ix+611. (New York and London: McGraw-Hill Book Co., Inc., 1941.) 42*s*.

PHYSICAL chemistry started with van t' Hoff's discovery (1884) of the reaction isochore, which, fundamentally, stood on the same ground as the gas theory of Maxwell and Boltzmann. In the field of reaction rates the ideas of this period produced the mass action law of Guldberg and Waage and the exponential equation of Arrhenius.

Planck's quantum theory (1900) led to a new departure in physical chemistry. Its application to thermodynamics resulted in the third law, which defined in principle the position of chemical equilibria in absolute terms. There occurred, however, no corresponding progress in the field of reaction rates; in fact, for the time being, the nature of chemical change became rather more obscure. Between the classical Maxwell-Boltzmann view of atoms in perpetual motion passing continuously through every conceivable configuration, and the rigid set of stationary states postulated by quantum theory, there was an essential contradiction which paralysed, rather than stimulated, inquiries into the ways by which atoms can pass from one molecular partnership into another.

Quantum mechanics opened a third phase of physical chemistry, in which the theory of reaction rates received a new stimulus. Heitler and London's theory of the electron-pair bond and London's treatment of the three-electron and four-electron problem gave a general— though to begin with naturally somewhat crude—conception of the way in which atoms may become engaged and disengaged in the course of chemical reactions. Since 1929 a steady development has been going on from this starting-point, in which the work of H. Eyring has played the most important part. "The Theory of Rate Processes" was written, as the introductory chapter tells, in the conviction that this last phase has now reached some conclusive results. The book is meant to demonstrate this.

We are thus presented here with a survey which attempts a synthesis of many single contributions in the light of one set of propositions. It is an authoritative effort carried out with vigour, skill and profundity, and its result is a unique achievement. There can be no doubt that all future inquirers in the field of reaction theory will have to start by consulting this work.

Yet there remains the question: Does the book, and the work reviewed in it, fulfil the desire for a theory of chemical reactions?

The answer is not simply affirmative. There is no single new law claimed here of the kind of the reaction isochore or the third law. We could predict all chemical reactions, if we could solve the quantum mechanical equations; but that, of course, is a truism. The purpose of the new theoretical apparatus is in fact to find approximate solutions for specific classes of integrals, often circumventing part of the problem by introducing empirical values for terms which cannot be evaluated from first principles. The quasi-empirical method for calculating activation energies, the theory of the activated complex, both in its statistical and its thermodynamical forms, represent a scaffolding by which the general theorems of quantum mechanics can be brought to bear on concrete 'rate processes'. The real question is, therefore, how far they have succeeded in this function.

One claim, I think, can now be made in this respect without much danger of a challenge to the contrary. The modern theory of reaction rates has finally succeeded in establishing itself as an indispensable method of thought. It has become the recognized tool for any detailed speculations in the mechanism of chemical change; in fact for any intelligent appreciation of the subject. I think that in addition to this a good deal of sound semi-quantitative confirmation has also been obtained. But I would hesitate to pronounce on its finality. In many cases we are clearly yet at the stage where we must be satisfied to account for the observed phenomena, without claiming much certainty for our explanation.

I regret that the juncture between the new theory of reaction rates and the 'electronic theory' of Flursheim, Lapworth, Robinson and Ingold still does not seem very close. The future valuation of the new ideas may largely depend on the extent to which they will prove able to explain more of the remarkable rules which the organic chemist has discovered and has not yet related with any degree of precision to the interplay of atomic forces.

In the light of present achievement and in the hope of further advance, we may recall for a moment the general expectations which have been entertained on the subject of theoretical chemistry for the last thirty years or so. It was about 1912 that I first heard it said in jest, that "You need not bother any longer to learn chemistry, because soon it will all be predicted mathematically". I have heard this kind of joke many times since. Meanwhile it seems to become quite clear that chemistry will never become predictable mathematically; and that, in fact, we have rather to make mathematical physics —in a sense—more chemical. We have to discover a set of empirical simplifications—corresponding to the nature of the chemical properties of matter—which will allow us to crystallize the general equations of atomic physics into a form readily applicable to chemical changes. The "Theory of Rate Processes" will long remain a landmark on this line of progress.

M. POLANYI.

PARACELSUS AS PHYSICIAN

Four Treatises of Theophrastus von Hohenheim called Paracelsus

Translated from the original German, with Introductory Essays, by C. Lilian Temkin, George Rosen, Gregory Zilboorg, Henry E. Sigerist. Edited, with a Preface, by Henry E. Sigerist. (Publications of the Institute of the History of Medicine, the Johns Hopkins University, Second Series: Texts and Documents.) Pp. xiii+256. (Baltimore, Md.: Johns Hopkins Press, 1941.) 3 dollars.

"THE most striking figure among the physicians of the sixteenth century, perhaps in the whole of medical history, is Theophrastus von Hohenheim, called Paracelsus (1498–1541)". This is the considered verdict of the best English historian of medicine. Paracelsus died at the age of forty-eight, after a wandering life, part of which was spent in the mining town of Villach, where he not only studied the diseases of miners, but also acquired a knowledge of chemistry. Some three hundred works have been attributed to him, of which one third have been printed and perhaps not more than fifteen are genuine. He borrowed much, without acknowledgment, from Basil Valentine.

A keen student of the natural sciences, but of a wild and violent temper, Paracelsus attacked Galen and the Galenic tradition with unbalanced aggressiveness. In this way he acted as a kind of bomb, demolishing the old structure that it might be rebuilt by William Harvey and his successors. He was, however, too much of a religious mystic, with his four "pillars" of medicine—philosophy, astronomy, alchemy and the virtue of the physician—to become the founder himself of a new order of medicine. He speculated as rashly as did Galen, far more so than the Hippocratics, whose works present a remarkable contrast in their scientific soberness to the fanciful dogmas of this physician born two thousand years later.

The book under review, the first modern translation into English of any works of Paracelsus, is a labour of love to mark the four-hundredth anniversary of his death. Like all such labours it has been carefully and well done by the four collaborators. From it the reader may gather both the merits and faults of "Lutherus medicorum", as Paracelsus was styled, his interest in drugs, occupational diseases and psychiatry, his self-assurance, conceit and tendency to wild speculation. The fourth treatise of the book is scarcely medical at all, but throws light on the mystic belief in sylphs, nymphs, pygmies and salamanders, the spirits living in the four so-called elements.

Paracelsus was no bigoted adherent of the doctrine *nihil in intellectu nisi prius in sensu*. He was convinced that there is a higher knowledge than that coming through the senses, a knowledge coming direct from God through the agency of the Holy Spirit. A similar belief has been held by many great minds with the religious instinct strongly developed. It inspired the work of Plato and St. Paul, while in a humbler sphere it has guided the lives of millions of simple folk, who have been as sure of its truth as of their own existence.

W. H. S. JONES.

THE INDIAN FARMER

Sons of the Soil

Studies of the Indian Cultivator. Edited by Dr. W. Burns. Pp. ix+128+44 plates. (Delhi: Manager of Publications, 1941.) 2.6 rupees; 4*s*.

INDIA and her politicians, not without good reason, have been much in the news during recent months, but, in the long view, it is her peoples, comprising a vast and varied agricultural population, who will dominate the historic scene. For this reason the attractive and well-illustrated little volume, edited by Dr. Burns, agricultural commissioner with the Government of India, should be carefully read at the present time. The Indian cultivator "is India outside of the towns". His agricultural difficulties are great and of long standing; they are as varied as the territory in which they arise. The object of the sketches in the volume under review is, among other things, to get rid of the idea of the Indian cultivator as a person or type, and to show something of the variety of individuals and classes who cultivate the soil of this immense country.

The several sketches or essays have been written by competent people possessing intimate knowledge of particular regions and their inhabitants, both British and Indian names appearing in the index of contributors. It is a rich and colourful assemblage, in which one notes many points of difference but, fundamentally, with a vein of similarity throughout. From the objectively written articles one forms an impression of an essential plainness of life wherever the cultivator is at work, a similar hard wrestling with the difficulties of soil infertility and the uncertainty of climate; but throughout there is a philosophy and attitude of mind which, financial indebtedness notwithstanding, enable those sons of the soil to live their lives cheerfully and in a spirit not lacking in neighbourly helpfulness.

A THEORY OF THE STRENGTH OF METALS*

By SIR LAWRENCE BRAGG
O.B.E., F.R.S.

THE shear stress at which a metal passes beyond the elastic range and begins to yield is ill-defined. It is very small for highly perfect single crystals, and less for an annealed polycrystalline specimen than for one which has been hardened by cold work. It has often been pointed out that there is no elastic limit in a typical plastic metal, since the apparent stress at which the metal begins to yield depends upon the sensitivity of the means for detecting very small rates of flow. Nevertheless, the elastic limit and ultimate strength of metals can be stated in round figures; were it not so, the engineer would have no basis for his calculations.

It is generally accepted that the effect of plastic deformation by cold-working is to break down each of the crystalline grains, which are seen in polished and etched specimens, into a mosaic of much smaller crystal fragments with different orientations. These fragments have been termed 'crystallites' by some X-ray workers, though this term was originally coined for crystal skeletons, and is so used by the metallurgist (cf. Desch, "Metallography", p. 137), or is used in some countries to denote the crystal grains themselves. They will be termed 'mosaic fragments' here, in order to avoid specifying too clearly their physical nature. Their size may be estimated by the broadening of X-ray diffraction lines which they produce. Progressive plastic deformation of an annealed metal at first breaks down the crystal grains into ever smaller fragments, but there appears to be a limit to the process. An excellent summary of the X-ray diffraction phenomena was given in a paper in 1938 by H. J. Gough and W. A. Wood in the *Journal of the Institution of Civil Engineers*. The changes in crystalline structure during the progressive cold-working of pure copper, silver, nickel, aluminium, molybdenum and iron have been studied in a series of very interesting papers by W. A. Wood[1], and he gives estimates for the lower limiting size of the 'crystallites' ranging from 10^{-4} cm. for aluminium to $0 \cdot 7 \times 10^{-5}$ cm. for copper. Some speculations about the nature of this fragmentation and the factors which govern this lower limiting size are put forward at the end of this paper.

It is not easy to separate the effects of strain, lattice curvature and crystal size upon the X-ray line broadening. However, a picture such as is represented in Fig. 1 will be assumed, where the heavy outlines are those of the original crystal grains revealed by etching, and the pattern inside the grain represents the mass of mosaic fragments or crystallites produced by the deformation, with orientations shown by the hatching, which may vary over a certain range (30° in the figure) or in an extreme case may be quite random.

Although the elastic limit of a metal is so ill-defined, this does not rule out the possibility of a strict relationship between this limit and the average size of the mosaic fragments. Variations in this limit from specimen to specimen of pure metal may be ascribed to differences in this size, and the increasing stress which the metal can withstand with increasing deformation may be ascribed to a corresponding decrease of average fragmentation size during the experiment. It is the purpose of this communication to establish such a relationship. The treatment bears some formal analogies to the well-known treatment of the mechanism of plastic deformation of crystals given by G. I. Taylor[2], but it is based on a somewhat different physical interpretation and it is hoped that it has certain novel and suggestive features.

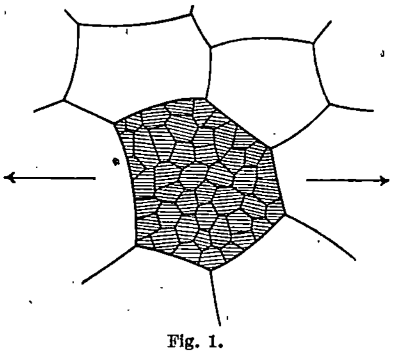

Fig. 1.

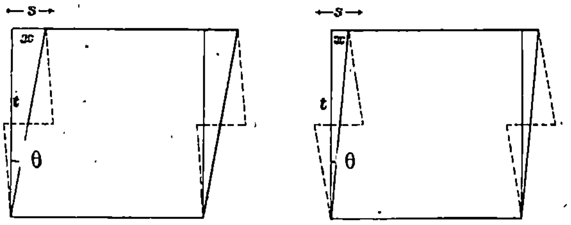
Relation between Elastic Limit and Average Mosaic Fragment Size

In the first place, if Wood's figures for the lower limit of fragment size be accepted, a very simple treatment shows that they lead to an estimate of ultimate strength which is of the same order as that which is observed. Fig. 2 represents a fragment, for simplicity supposed to be a small cube of volume V and side t, embedded in the metal matrix. Also for simplicity it is supposed that the general shear strain of the metal in which it is embedded is parallel to the glide planes of the fragment and is in the direction in which glide takes place. The displacement of the top of the fragment with reference to the bottom is given by $x = \theta t$, when θ is the shear angle. Let s be the interatomic distance, which is the unit of displacement of the glide process. It will be clear from Fig. 2 that the fragment, forced into this strain by the surrounding matrix, will not yield by gliding on any intermediate plane unless x is greater than $s/2$, because if x is less than $s/2$, the strain is greater after the glide than before it commenced. To put it formally, glide will only take place if it represents a release of energy, that is, if



$x > s/2$
Strain decreased by glide

$x < s/2$
Strain increased by glide

Fig. 2.

$$\tfrac{1}{2}n\left(\frac{x}{t}\right)^2 . V > \tfrac{1}{2}n\left(\frac{x-s}{t}\right)^2 V.$$

$$\text{or } x > s/2, \qquad (1)$$

n being the coefficient of rigidity.

---

* Substance of a lecture delivered at the Royal Institution on March 31.

This estimate of the critical value for x is a minimum, because the direction of shear has been taken to coincide with that of glide. Actually, glide has to take place along the most favourably situated plane and direction, which are in general inclined to the shear. To calculate the order of the effect, it may be taken that glide will not occur in this particular fragment until the general shear strain reaches such a value that

$$x \sim s.$$

All the fragments are subject to this condition. The whole metal will therefore withstand a shearing stress

$$T \sim ns/t. \qquad (2)$$

To take the case of pure copper, for example, for which $n = 4{\cdot}5 \times 10^{11}$ dynes per cm.^{2}, $s = 2{\cdot}56$ A., and according to Wood[1] $t = 0{\cdot}7 \times 10^{-5}$ cm. :

$$\begin{aligned} ns/t = 4{\cdot}5\times10^{11}.\ 2{\cdot}56\times10^{-8}/0{\cdot}7\times10^{-5} & \\ &= 1{\cdot}64 \times 10^{9} \text{ dynes per cm.}^2 \\ &= 1{,}640 \text{ bars} \\ &= 10{\cdot}6 \text{ tons per square inch.} \end{aligned}$$

The figures for several pure metals for which Wood gives a lower limit of crystallite size are as follows :

	t(cm.) Wood	n(dynes/ cm.^{2})	s(A.)	ns/t (bars)	ns/t (tons/ in.^{2})	Observed elastic limit (tons/ in.^{2}) Wood	Observed ultimate strength (bars)
Copper	$0{\cdot}7\times10^{-5}$	$4{\cdot}5\times10^{11}$	2·56	1640	10·6	—	2200
Nickel	$1{\cdot}2\times10^{-5}$	$7{\cdot}7\times10^{11}$	2·49	1600	10·3	—	5000
Silver	$0{\cdot}8\times10^{-5}$	$2{\cdot}9\times10^{11}$	2·88	1050	6·7	—	1300
Iron	$3{\cdot}2\times10^{-5}$	$8{\cdot}3\times10^{11}$	2·42	630	4·1	3·75	2500
Aluminium	$10{\cdot}0\times10^{-5}$	$2{\cdot}6\times10^{11}$	2·86	74	0·48	0·50	600

The figures in the last column represent ultimate strength as given in Landolt and Bornstein (maximum load before necking sets in) / (initial cross-sectional area). They cannot be directly compared ; they merely show that the calculated figures are of the right order. To obtain a satisfactory check, the crystallite size must be measured on the material which is just withstanding the stress. For example, Wood and Smith[3] give a stress-strain curve for pure aluminium, which shows an elastic limit for tension of 1 ton per square inch corresponding to a limiting shear stress of 0·5 ton per square inch, which agrees with the value 0·48 ton per square inch calculated on the basis of Wood's estimate of crystallite size in aluminium. Their corresponding figure for pure iron[4] is 7·5/2 = 3·75 tons per square inch, which also agrees with the figure 4·1 tons per square inch in the above table. Only the order of the agreement is significant.

The above simple picture of the condition which determines slipping must be modified because no account has been taken of the additional strain in the neighbouring crystallites produced by the dislocations at either end of the glide plane. Although no attempt is made here to calculate this effect quantitatively, the type of modification it will introduce can be seen as follows. Let it be supposed that the dislocation, of amount s, produces an additional strain sf at a point P in its neighbourhood when f is some function of the co-ordinates of P. The additional energy along the two dislocation lines each of length t is

$$\tfrac{1}{2}n\int\left\{(\theta + sf)^2 - \theta^2\right\}2t\,dA,$$

where dA is an area element. The total additional energy is therefore, by integration

$$\tfrac{1}{2}\,nt\,(2s\,\theta\alpha_1 + s^2\alpha_2),$$

where $\alpha_1 = 2\int f dA$, $\alpha_2 = 2\int f^2 dA$ are constants depending only on the function f. Hence the condition for slip becomes, putting $V = t^3$, $\theta = x/t$,

$$\tfrac{1}{2}\,n\left(\frac{x}{t}\right)^2 t^3 > \tfrac{1}{2}\,n\left(\frac{x-s}{t}\right)^2 t^3 + \tfrac{1}{2}\,nt\left(\frac{2x}{t}.s\alpha_1 + s^2\alpha_2\right)$$

$$\text{or } x(1 - \alpha_1/t) > s(1 + \alpha_2)/2.$$

If t becomes so small that α_1/t approaches unity, the strain cannot be released by slip ; in other words, the material behaves in a brittle manner. If it is well within the plastic range, it may be assumed that $\alpha_1/t \ll 1$. This would not be true if one assumes Timpe's formula (G. I. Taylor, p. 376, *loc. cit.*), where f is of the order $1/r$, but there is probably some local atomic adjustment in all dimensions which eases the strain at the ends of the glide plane. No estimate of α_2, which measures the energy of a dislocation apart from any pre-existing strain, is made, but if it is small it follows that

$$\text{Limiting stress } T = \alpha\, ns/(t-t_0), \qquad (3)$$

where the constant α is certainly greater than 1/2 and is probably about unity, and $t_0 (= \alpha_1)$ is a lower limit of fragment size below which the metal becomes brittle.

A formula of the same general type as (2) is given by G. I. Taylor (*loc. cit.*, p. 379) for the condition that two 'dislocations' should be able to pass one another. The critical shearing force to affect this is given by

$$S = \frac{\mu\lambda}{2\pi h},$$

where μ is the coefficient of rigidity, λ the interatomic distance, h the nearest distance of the slip planes on which the dislocations are situated. I prefer the present way of regarding the problem, because it makes no postulates about the arrangement of the dislocations, but is based on the average fragment size for which there is direct X-ray evidence.

One point may be noted briefly. The yield of one fragment imposes an extra strain on its neighbours, as has been seen above. If they are already strained nearly to the limit, they will yield in their turn. Thus an avalanche of yielding will run right across an individual crystal grain along the mean direction of the glide planes as shown by the arrows in Fig. 1. It may be many fragments in breadth and so of macroscopic size. The explanation of the slipband in some such way has often been proposed, but the above picture perhaps explains it rather more realistically.

To sum up, the point of view adopted here is that it is possible to calculate the limiting stress a metal will stand elastically without making any assumptions about the way glide is initiated or travels in a single crystal, or about the forces required to produce it, beyond assuming they are very small, which is known to be the case. If a mosaic fragment is strained beyond the point at which a glide of one interatomic distance will reduce the strain energy, it is unstable and the glide is certain to take place. This condition by itself suffices to determine the elastic limit. Much emphasis has been laid in the past on the necessity of studying the gliding process and strength of a single crystal before the polycrystalline metal can be understood. It would appear that, paradoxically, the reverse is the case. The strain hardening of a single crystal is a complex process depending on the progressive deterioration of its perfection, whereas the cold-worked metal has attained a constant statistical average as regards the size of its mosaic fragments, and thus attains the constant strength calculated here.

Physical Nature of the 'Mosaic Fragments' or 'Crystallites'

The cold-worked crystal grain is pictured above as a mosaic of fragments meeting at well-defined interfaces, each having a perfect crystalline pattern throughout its own domain. It is not intended to convey the idea that this is necessarily the true picture. It has certain attractive features which I outlined in a note on "The Structure of a Cold-worked Metal"[5]. The structure was there described as resembling a foam, with movable boundaries able to take up positions of equilibrium. It was shown that such a structure, if momentarily broken down into a very fine scale, would rapidly recrystallize at first up to a certain characteristic size, whereupon the process would become so slow as practically to cease. Some such effect must exist, in order to account for the constant mechanical strength of the cold-worked metal which is characteristic of it and persists, but other models may give an equally good explanation. What is observed is a broadening of the X-ray line, which may be caused by small crystal size, or by some distortion of the lattice with its consequent strains. The formula (3) for the stress which the metal will withstand is independent of the precise picture of the nature of the fragmentation. Let us suppose, for example, that the cold work produces, not a mass of perfect fragments differing in orientation, but a crimping or waving of the lattice planes so that successive small regions make an angle with each other, but all crystalline coherence of one with the next is not destroyed. The constant t, interpreted above as the dimensions of a fragment, would then become the repetition interval of the crimping. Such a modulation of the perfect crystal spreads the sharp X-ray reflexion into side-bands. By optical principles, the spread of these side-bands due to this modulation at intervals of t is the same as the broadening of an X-ray line produced by independent perfect crystals of width t, although there are certain rather subtle differences in the X-ray diffraction effects which may throw light on the true nature of the fragmentation. The point to be emphasized, however, is that if we suppose the crimping to limit the elementary gliding process to regions of dimensions t, the same dimension t will also determine the broadening of the X-ray lines, and the formula (3) above will hold.

In conclusion, I wish to express my warm thanks to Dr. E. Orowan for helpful discussion and criticism. Dr. Orowan's note on slip-bands in NATURE of April 12, 1941, p. 452, suggested the fundamental idea on which the above explanation of the strength of metals is based.

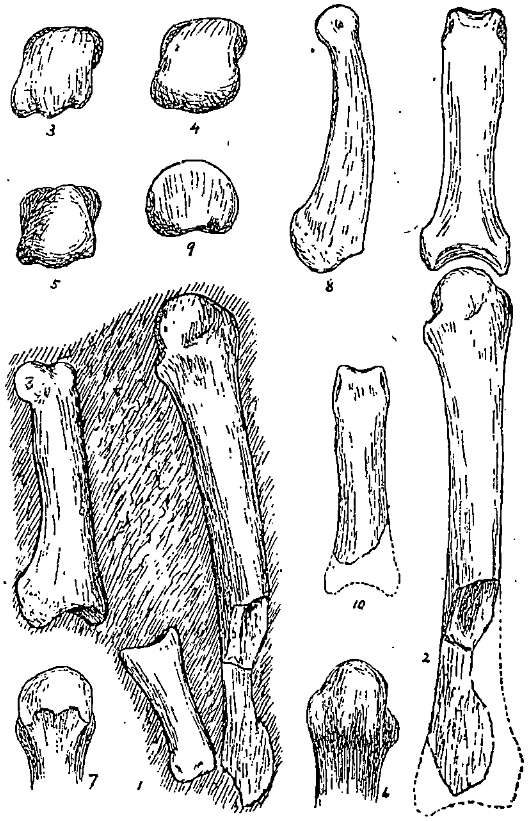
THE HAND OF THE APE-MAN, *PARANTHROPUS ROBUSTUS*

By DR. R. BROOM, F.R.S.
Transvaal Museum, Pretoria

THE block of bone breccia in which the beautiful skull of Paranthropus was found has already yielded us the distal end of a humerus, the proximal end of an ulna and two toe bones. The matrix on which the maxilla rested has remained until recently untouched, as it retains the excellent impressions of the premolars and the first and second molars. In this matrix there was exposed a little piece of bone which I thought might prove interesting. On following it in, I found it was part of the well-preserved second metacarpal of the left hand. Close to it I also found two phalangeal bones, and in another piece of matrix much of another phalangeal bone. The distal end of the metacarpal lay within a millimetre of the maxilla.



FINGERS OF PARANTHROPUS. NATURAL SIZE.

1. Bones in relative position as found.
2. 2nd left metacarpal and proximal phalanx of Paranthropus.
3. Distal end of 2nd left metacarpal of Paranthropus.
4. Distal end of 2nd left metacarpal of Bushman.
5. Distal end of 2nd left metacarpal of baboon.
6. Palmar side of distal end of 2nd metacarpal of Paranthropus.
7. Palmar side of distal end of 2nd metacarpal of baboon.
8. Side view of proximal phalanx of 2nd left finger of Paranthropus.
9. Proximal end of proximal phalanx of 2nd left finger of Paranthropus.
10. Probably proximal phalanx of 4th finger of Paranthropus.

The metacarpal bone is perfect, except for the loss of the proximal end. It is long and slender, and not like the metacarpals of any of the living anthropoids.

It is more like the metacarpal of the Bushman, but longer and more slender. It is quite certainly not a human metacarpal. In a number of respects it resembles the baboon metacarpal, but it is about a quarter larger than the corresponding metacarpal in a large male *Papio comatus*. The distal end of the metacarpal is essentially cercopithecid in character, and there can be little doubt that there must have been as in the baboon a pair of sesamoids.

We know that in man a pair of sesamoids is present at the distal end of the first metacarpal, and one is frequently present at the distal ends of the second and fifth metacarpals. But radiologists have recently found that other sesamoids are also not infrequently present. There may be one or a pair of sesamoids present at the distal ends of all the metacarpals. It thus seems probable that the ancestor of man had a pair of sesamoids at the distal ends of all the metacarpals, as in the baboons.

The large phalangeal bone is almost certainly the proximal phalanx of the same finger as the metacarpal. It is almost typically cercopithecid in structure, but deeper proximally than in the baboon.

There will doubtless be those who will argue that these skeletal remains do not belong to the skull. I understand that opinions have been expressed that the humerus may be that of a chimpanzee, or even that it is human; and possibly it will be held by some that the hand bones I have discovered are those of a giant baboon. All these skeletal remains were found in the same piece of bone breccia, which is less than a cubic foot in size and which gave us the Paranthropus skull; and as the metacarpal is certainly that of a large Primate, it seems to me probable that the hand, the skull, the humerus, the ulna and the toe bones are all the bones of the skeleton of one individual. If this is so, we get a few interesting facts about the structure of this remarkable ape-man.

A giant Pleistocene baboon, *Dinopithecus ingens*, has, however, been found in the Transvaal, but it is not known to occur at Kromdraai; the only large baboon at Kromdraai being *Parapapio major*, which is not larger than the living baboon. If ever teeth of Dinopithecus are discovered at Kromdraai, the question will of course arise as to whether these hand bones, though closely associated with the Paranthropus skull, are not really bones of the hand of Dinopithecus.

At Sterkfontein there has been discovered a large baboon-like pelvis, with a femur and three vertebræ. These may be parts of the skeleton of Dinopithecus. The femur is considerably smaller than the supposed Plesianthropus femur, and more baboon-like. It is thus possible that Dinopithecus may have been contemporary with Paranthropus, and it may be argued that the finger bones are those of Dinopithecus.

It may be many years before we get a hand of Dinopithecus in association with a skull or teeth, and even if we do I do not see how we shall be able to prove that it is not a hand of Paranthropus in association with a Dinopithecus skull or teeth, unless we also get an associated humerus.

From the shape of the distal end the metacarpal is manifestly a metacarpal of the left hand, and the only point that might be debated is whether it is a 2nd or a 5th metacarpal. The shape of the distal end seems to leave no doubt that we are dealing with a 2nd metacarpal; and if it is a 2nd metacarpal the posterior part of the bone is quite differently shaped from that in the baboon. If we are dealing with a 5th metacarpal, whereas the shaft is like that of the baboon, the distal end is very different. If we compare the bone with that of the Bushman, we find a considerable agreement except that the bone is longer and more slender, and the distal end has clear evidences of there having been two sesamoids in association. All the available evidence points to a closer affinity with the Bushman metacarpal than with that of the baboon, except that as there have been two well-developed sesamoids the distal end resembles considerably that of the baboon. The sesamoids have also led to the proximal end of the phalanx being more baboon-like than man-like.

The little phalangeal bone found beside the metacarpal is manifestly a first phalanx. It cannot be a thumb-phalanx. It might perhaps be the first phalanx of the 5th finger of Paranthropus. If so, the 5th digit would be remarkably small and short. There is, however, another possibility, and even a probability. In the same block of matrix is a fragment of the frontal bone of a small 'baboon'—probably *Parapapio angusticeps*—a small 'baboon' which is fairly common at Kromdraai; and it seems that the most natural determination of this small phalangeal bone is that it is a phalanx of *Parapapio angusticeps*.

This hand is closely associated with the skull of Paranthropus, and it seems to me so much more probable that the hand belongs to the same individual as the skull that I believe that this is the hand of Paranthropus, even though it has some cercopithecid characters. In any event it seems but right to figure the specimens and place the facts before the world that others can consider the matter.

We know that the milk teeth of Paranthropus and Australopithecus have retained many cercopithecid characters lost in the living anthropoids, and we need not be surprised to find cercopithecid characters in the metacarpal and phalangeal bones.

If the hand is that of Paranthropus, then we have a type that has no close resemblance to that of the living anthropoids, but a type somewhat intermediate between that of the baboon and man. This does not mean that Paranthropus is descended from a baboon, but only that the ancestor had retained some cercopithecid characters.

Until recently I inclined to follow Gregory in believing that man has been derived from a primitive Dryopithecid; but as the living anthropoids and most of the fossil Pliocene forms have teeth characters not found in man and the Australopithecines, I now think it more likely that man and the Australopithecines came from a pre-Dryopithecid, a view which is favoured by Weidenreich, and a little like the views of Osborn and Wood-Jones. If the hand is that of Paranthropus, we have additional evidence in favour of this view.

If we compare these hand bones with the large bones of the gorilla, chimpanzee and the orang, we might readily conclude that they are too small for the hand of an animal about as large as a large chimpanzee. But we know that Plesianthropus, which is allied to Paranthropus, had an os magnum even smaller than that of the Bushman, and had thus almost certainly a small, rather delicate, hand. We know that the supposed Plesianthropus os magnum cannot possibly be the os magnum of a baboon; and we are thus apparently justified in holding that the large finger bones very closely associated with the Paranthropus skull really belong to Paranthropus.

SCIENCE AND SOCIETY

By DR. F. SHERWOOD TAYLOR
Museum of the History of Science, Oxford

AT the twenty-first annual general meeting of the University Catholic Federation of Great Britain, which took place at Birmingham during April 10–12, three conferences were held on the theme of "Science and Society". The first conference was concerned with the question, "What is Science ?", and under the chairmanship of Prof. Thomas Bodkin, professor of fine arts in the University of Birmingham, was opened by a paper from Dr. F. Sherwood Taylor, curator of the Museum of the History of Science of the University of Oxford, entitled "An Historical Survey of the Rise of Science".

Dr. Sherwood Taylor pointed out that the rise of science was contemporary with that of civilization. Its first stage was the rational treatment of crafts and the study of phenomena which had religious significance. The Egyptians and Chaldeans were the chief originators of science in its practical aspect, but theoretical science, the philosophy of Nature and natural causes, had to await the genius of Greece, which excelled in the abstraction of general principles, yet was defective in its rash assumption of a universal correspondence between that which the mind conceived as fitting and that which in fact existed. The Greeks, and the immediate heirs of their achievement, excelled in all which could be investigated geometrically, but were comparatively deficient in those sciences which could be acquired only through the discipline of the laboratory, which began to have importance only when the wave of ancient science was fast receding. In the period A.D. 300–1100 Europe was barren of scientific achievement, because wholly preoccupied with political reconstruction, and with the enormous implications of the central fact of human history, the Incarnation. The attitude of this period towards natural science was that speculation with regard to it in no way furthered a blessed life, and so was a culpable waste of time and talents. Meanwhile, the philosophy of Greece blossomed again in Islam, and when it came to Western Europe and was assimilated with Catholic doctrine, Greek science came with it. In the thirteenth century such men as Albertus Magnus, Roger Bacon, Peter Peregrine, Mondino, and the numerous alchemists gave good hope of an age of experimental science. But it was not to be, and the wave of modern science which is yet gathering force took rise from a different source, the Platonic speculations of such men as Marsilio Ficino.

After a century or more, when science was regarded, with natural magic, as an arcanum, the genius of Galileo demonstrated the practice of modern science, while Francis Bacon enunciated its theory. Here came perhaps the most portentous step in world history, the separation of natural knowledge from philosophy and religion. Natural knowledge, by limiting its objective, became cumulative, and ever more swiftly grew to its present bulk. The economic application of science, previously unimportant, became finally predominant. Industrial civilization led to the horrors of exploitation in the nineteenth century, and each succeeding half-century has brought to mankind a more numerous crop of revolutionary inventions. The next half-century is likely to transform the world even more profoundly than the last, for good and evil: Are we to let it proceed without rational direction or control ?

The second paper in this conference was given by the Rev. J. Leycester King, S.J., professor of psychology at Heythrop College, who took for his subject "Science and Reason". He emphasized that a large part of the world's troubles can be traced to a desertion of scientific ideals, the substitution of illusion for fact. Science is alive to the discord and irrationality of the modern world, and to the implications of the policy of tampering with truth, which policy is the antithesis of science. Yet most of those who seek a remedy in science are themselves, consciously or unconsciously, subject to the illusion, long discarded by philosophy, that only what is mediately or immediately observable is real. Science must realize that there are unobservables which are real, and which are within the competence of human thought to study and systematize. These matters are now reserved to philosophy and theology. Science, divorced from these, has made rapid progress, it is true, but this progress has only been possible because science and its workers are embedded in a civilization based upon Christian principles. The knocking away of the Christian foundations of our civilization has already resulted in self-deception, illusion, wishful thinking and unreason, and though we may point in priggish horror at the deliberate distortion of truth practised by our enemies, we are not to forget that we are ourselves already far down the slope of disintegration.

We have been living on our spiritual capital. Our need is not of more science, or of less science, but of formulating an end and meaning of life, perceiving a unity in which the harmony of the manifold appears. Our knowledge of this unity will but increase the purity and vigour of science, for the truth inherent in the whole must subsist in the sub-wholes which form our field of investigation. Science must be re-married to philosophy, which alone can provide a datum-line of immutable principles, about which oscillate the dogmas of science, of which so many have been proclaimed as infallible, then modified, and at last abandoned. Separated, philosophy and science must fade and pine: united they have the grandest of futures.

The second conference, under the chairmanship of Dr. Hugh O'Neill, chief metallurgist of the London, Midland and Scottish Railway, was concerned with the social impacts of science, and was opened by Prof. Louis Renouf, professor of biology at University College, Cork, with a paper entitled "The Influence of Modern Biology". Modern biology, he indicated, begins with Darwin, and since its inception has exerted the most conspicuous influence on human thought. Darwin's notion of organic evolution was intended to be, and in fact proved, a most valuable working hypothesis for science, but in the able hands of T. H. Huxley, and later as "travestied by Haeckel", it became the foundation of the materialistic biology which has vastly influenced the popular beliefs of the modern world. Biology and physiology have entered the field of human behaviour; the attempts made to account for moral codes in terms of endocrine glands are good examples of their more extreme methods. To-day social biologists have enormous prestige and popularity, and problems of human society have come to be thought of in biological terms. It is of the greatest importance, then, that the biologist should be fitted for his present responsibilities. But, in fact, the greatest part are reared in a materialistic atmosphere, and acquire a philosophy which is manifest in the first-class research work which is to-day being presented in an irrelevant matrix of Marxian philosophy. Catholics, and indeed Christians in general, are at fault in looking upon all forms of science with a timidity that is a relic of a past defensive attitude. There is a great need for more Christian men of science, especially biologists, who may oppose a truly personalist attitude to the decadent views falsely put forward as the answers of science to the human problems of marriage, education and family relationships. One of the most important steps to be taken is the proper education of medical men. The medical course is long, and commonly admits of few but professional studies, whereas it is most desirable that medical men should have some knowledge of sociology, the arts and the elements of philosophy. A preliminary year's course of humanistic studies would be of great value to men who will have so important a position in the social structure.

There followed a paper on "Science and Man" by Dr. H. P. Newsholme, professor of hygiene in the University of Birmingham. The most important effect of science on the community was its example of single-minded search for truth, and discarding of emotional and personal feelings; but this setting aside of all but the material aspect of things, though it arise from a recognition of the incapacity of science, may lead to the implicit assumption that the material aspect alone is worthy of consideration. This limitation of outlook has led to correspondingly defective results. Thus Freud did good service in opening up the subconscious, but failed to recognize in it an avenue of God's approach to man. In the region of the physical life and of social environment the debt of humanity to science has been incalculable. But though the health and comfort of man has been increased, the troubles of his spirit are left untreated.

The great prestige of science has led society to respect the opinions of its workers, and their implicit materialism has contributed to the formation of a materialistic society, which in turn rears more materialistic scientific workers. Not only science, but also almost every human activity, has become dissociated from religion, and the immediate consequence has been their exploitation by the selfish. Scientific agriculture has led to denudation and sterility; family limitation is depleting the population and degrading it by separating the pleasures of sex from its responsibilities. Furthermore, the exaltation of the physically fit as alone worthy of survival threatens the world with the arrangement of mating on physical grounds, with sterilization of the so-called unfit, and with euthanasia, which leads by a short step to the deliberate 'elimination' of the aged, mentally deficient or incurable. In the realm of ideas the effect has been even to extend natural law beyond its function, which is the summation of past events. Such events as find no place in the records of science, for example, miracles, such as the Resurrection, the greatest of them, are sometimes denied; and theories, such as that of organic evolution, are extended from body to mind. If science had retained its association with religion, it might have grown more slowly, but the product would have been richer and more significant, and the world would have been protected against the worst types of exploitation of the powers of science.

The final conference was presided over by the Right Rev. Bernard Griffin, Bishop Auxiliary of Birmingham. The Rev. Philip de Ternant contributed a paper on "The Place of Science in Education". His title, he said, was not science in the school, which is another subject. At the time of Alcuin the concept of a scholar was primitive but comprehensive. The old Trivium and Quadrivium contained the germ of scholasticism and of *universities*: it involved recognition of the *unity* of the *universe* and of the spirit of man. One idea may be seen to underlie these three forms of a single word. As material knowledge increased, specialization became necessary, but to-day's is much overdone in response to the utilitarian age. Our task is to create a reversion to the older type of scholar and to re-integrate the scattered elements of knowledge, now known only collectively as science. The great specialists are noteworthy for the breadth of their basic knowledge, but men of science generally lack philosophy to-day. The true purpose of a university has been disnatured by fetishes, popular and scholastic. The width of outlook and general interest formerly displayed in the older "Academes", from the Royal Society down to local field clubs, and in the followers of nature hobbies in the family circle itself, is much needed to-day.

The Rev. Philip de Ternant advocated the 'perennial' philosophy of St. Thomas Aquinas and his modern followers, such as Maritain, in opposition to the widespread aberrations of to-day, and asked for a primer or handbook on the subject adapted to the use of science students. He regretted the obscurantism of the public and of certain pious people. St. Thomas had established that the study of natural science is a religious duty, as leading us, first to consideration and admiration of the Divine Wisdom, thence to reverence, fear and especially love, when the goodness and beauty of created things attracts the souls of men and leads to a comparison of the same things in a higher form in God; finally it sets up in men a certain similitude of the Divine perfection and wisdom. So, also, a wrong notion of the nature of creatures leads us to think they are all that exists, and that men are subject to laws which do not exist. So, argues St. Thomas, that opinion is false which says that it matters nothing to religious faith what anyone thinks of creatures, so long as he is right with God; for error concerning creatures leads to a false idea of God, and so leads minds away from Him. Therefore scripture threatens with penalties, as if they were pagans, those who have a false idea of natural facts: "Because they have not understood the works of the Lord, and the operations of his hands: thou shalt destroy them and shalt not build them up" (Ps. xxvii, 5).

QUANTITATIVE AND QUALITATIVE METHOD IN SOCIOLOGICAL RESEARCH

THE principal item on the Saturday (April 11) meeting of the British Psychological Society at Brighton was the open discussion in the evening between Mr. Henry Durant of the British Institute of Public Opinion, and Mr. Tom Harrisson of Mass-Observation. Mr. Durant opened the discussion by supporting the proposition "that Empirical Methods in the Social Sciences should be Predominantly Quantitative".

Social scientists should, in their empirical work endeavour to employ methods and concepts producing quantitative results. In Mr. Durant's view, organized science in the physical world is based upon measurement. These measurements can be tested and verified because they are based upon units of measurement which are objective and can be handled by any investigator. By insisting upon the quantitative method and developing its use in every direction possible, more and more phenomena are being reduced to quantitative terms. Biology took an immense step forward when genetics with its statistical basis was developed. Sound has been provided with its unit of measurement and is but the last in a list of qualities which can now be handled quantitatively. It is true that some physical sciences, for example, physiology, are not, at the present time, predominantly statistical in character. It is also true that the work of the biochemist and the crystallographer is rapidly providing a quantitative, mathematical basis for sciences such as physiology.

In the social sciences, Mr. Durant said, it is possible to point to quantitative elements in a discipline so 'qualitative' as psycho-analysis. Freud develops the concept of displaceable energy which can attach itself to either the ego or the id. If there is reality in this concept, units of measurement will inevitably be developed, and actually work along these lines is being done at the present time. Prof. J. D. Bernal, in a recent paper read before the British Association, discussed the importance of obtaining statistical data by means of social surveys. "It is true that we have not got accuracy to seven figures, but without a snap survey action has to be taken with no figures at all, and even one figure arrived at roughly marks an enormous improvement, mathematically an infinite gain."

Mr. Durant thinks no one should hope that social science can be reduced solely to statistical data. In every investigation the man of science, whether or not he is aware of it, is employing a social theory. The problems he investigates, the concepts he adopts, are in all cases part of a much larger whole which, when consistently extended, temper of the physical scientist. He must try to test his hypotheses by observation, since experiment is largely denied to him. It is no argument that the social sciences are still young and must, therefore, be content with the qualitative methods which formerly characterized all sciences. The history of science indicates that progress is most rapid when there is the most vigorous insistence upon exact statistical measurement. Often the unit of measurement is difficult to develop and the technique of measurement presents even greater problems. It is the task of the social scientist to overcome these difficulties in his own field, for only by these means will he be able to eliminate the subjective bias which characterizes so much work which is being done at the present time in the social sciences.

Mr. Tom Harrisson, opposing Mr. Durant's arguments, stressed first of all the scope of disagreement and discussion. He agreed, of course, that quantitative methods are essential in all empirical studies. The difference of opinion here was not on the method but the emphasis; he rejected the conception that such research *must* be predominantly quantitative. It should be secondarily quantitative. Parallels with the physical sciences can be misleading, because they have already a living tradition of procedure, accepted research standards, a great body of proved and agreed basic theory and theses. The social sciences, unfortunately, developed much later, and there is still no common outlook or interchange within the whole field of social research. Empirical work has been scrappy and diffuse; much of it has been quantitative and the proportion has increased very much lately. The War has given a big fillip to the social sciences, for in the present periods of vast social and psychological change, new problems present themselves to Government departments and others, which urgently require attention from the psychologist, the sociologist and the student of public opinion.

Social science has not been well enough based and organized to respond to this call equally at all levels. It has tended to answer largely with quantitative studies, often without adequate appreciation of the background facts; there has been a tendency to assume that because some human factor can apparently be measured in percentage terms, the study is, therefore, necessarily 'scientific'. The useful device known as the 'random sample' has provided an easy method for studying what people *say*. A few thousand interviews give a picture which will not be appreciably altered by interviewing the whole population. This quantitative method has, therefore, attracted much of recent social science. But because results are statistically consistent, it does not follow that they do not give a 'false' picture. By themselves they may be misleading, especially because we are still completely ignorant of the relationship between what people say to a stranger (the interviewer) and what they say to a friend; or between what people say, think and do. We are not yet in a position to know what weight can be attached to verbal behaviour; and at present we use interviews indiscriminately at our peril.

Mr. Harrisson feels that increased emphasis on this crude quantitative approach through the interview, without corresponding developments along other lines, such as observational technique, individual analysis, and penetration study of institutions, is unsatisfactory. In our present state of limited knowledge in social science, particular importance is attached to the full qualitative understanding of human phenomena, and at this stage the main function of quantitative methods, important as they are, is to act as a check, corrective and extension of the qualitative approach.

The social sciences have been slow to develop in Britain largely because the most educated and intelligent sections of the community are removed from the life of the mass of people who left school at or before the age of fourteen. It is difficult for the university professor to get down into the homes and hearts and minds of these people; few have done it objectively and over any length of time. Sociologists have long been conscious of this dilemma, and the sample method offered a way out—you ask people about themselves on a set questionnaire, or you pay others to go and ask for you, then tabulate the results in statistical detail. These results are important, in Mr. Harrisson's view, and there is room for many more of these studies, especially on the lines of the careful work done by the Wartime Social Survey; but to suppose that social science is thereby scientific, and that it can in fact progress far along primarily quantitative lines before the fundamental premises of method are proved (for example, the validity of social class, the distribution of temperamental types, geographical factors in outlook) is an abuse of the word 'science'. This word is too loosely used in the social sciences, where many of those concerned have not been trained in scientific method but on philosophical lines, so that they too easily accept decimal points as objective data.

Mr. Harrisson urged that we need less partisanship in social science, which is still embryonic. Every method, every study at this stage should be encouraged. But the primary and vital acts of empirical social study must always be qualitative. Mr. Harrisson welcomes the increase in quantitative methods, but deplores the growth of the idea that *only* such methods are socially scientific, an idea which is reflected in the wording of Mr. Durant's submission on this occasion.

In the discussion that followed, a wide divergence of view was expressed.

Dr. Gertrude Wagner spoke of the combined qualitative and quantitative method, and the need for social scientists to observe their own problems, to think them out qualitatively, then confirm their hypotheses by means of the quantitative method. She expressed the view that the only difference between Mr. Durant and Mr. Harrisson was as to whether there should be two hundred or two thousand interviews. Mr. Harrisson did not agree with Dr. Wagner on this, stating that there are sides of social science where no interviews are required, and current engrossment in the interview method was one of the things he was criticizing.

Dr. L. P. Richardson pointed out that the qualitative process is an essential initial step even in elaborate quantitative studies, as in the minutely accurate measurement work he had done in earlier days at the National Physical Laboratory. In comparing the weight of two bars of metal with the exactness required, it is still necessary to select the right bars for comparison by a qualitative act.

Dr. P. Senft discussed, in some detail, the philosophical relationship between quantitative and qualitative methods. Novelists like Proust and Stendhal have generally shown a far greater insight into human nature than psychologists and others approaching the same phenomena by quantitative methods.

Dr. Millais Culpin outlined some of his experiences during the work of the Industrial Health Research Board; he found the debate very like those he had heard long ago in medicine. It all boiled down to the old argument between those who were content to ask: What? and those who were also concerned to know: Why? The quantitative method is likely, if handled thoughtlessly, to lead into an interminable pursuit of the What, though the social sciences must be concerned very much with the Why.

Prof. M. Ginsberg expressed himself in favour of Mr. Harrisson's views. The idea that social research methods could be predominatingly quantitative, and that qualitative methods must merge into quantitative, is absurd. The suggestion that there is no real distinction between the two approaches is unsound. Quality does not pass imperceptibly into quantity. The two are distinct, and there are, in addition, many sorts of quality. The quantitative and qualitative approaches in themselves involve different concepts.

Dr. G. H. Miles's experiences in the field of market research have disillusioned him about crude quantitative methods in social study. He has seen elaborate statistical investigations which were built up on unsound methodological assumptions, such as a survey in which people were interviewed on certain food habits. They claimed to eat more butter than they could conceivably have consumed. For people often do not know what they really do, and more often give answers which show them as respectable citizens; people always want 'to show up well' in the interview.

Mr. Harrisson said that the discussion had cleared the air in a useful way. So long as social scientists were ready to interchange views and argue things out in a friendly atmosphere, so long would this be a vital and growing subject. There has been too much sociological over-sensitiveness to criticism in the past. Elasticity of outlook is necessary for the advance of any science; the development of science is largely the process of correcting somebody else's error.

Mr. Durant expressed the view that there had been a substantial body of agreement, and for his part he could not see any real difference of opinion, for he felt that in the end everything became quantitative.

PRODUCTION OF OPTICAL GLASS IN AUSTRALIA

By PROF. E. J. HARTUNG
University of Melbourne

THE manufacture of optical instruments of many kinds for the Armed Forces has become an important section of the extensive programme of munitions production undertaken by Australia in the present emergency. Of necessity, a new and complex industry of this type had to cope with many initial problems, among which the supply of suitable optical glass soon began to cause anxiety. Some glass was obtained from Great Britain and the United States, but in the dark months following the capitulation of France optical glass of good quality and in sufficient quantity was not obtainable. In certain directions, the need became so great that spectacle lenses were used, and blocks of glass for the prisms of tank periscopes had to be made by welding together many sheets of plate glass.

The decision to undertake the production of optical glass in Australia was made in the latter half of 1940, and subsequent events have shown most thoroughly the wisdom of this policy. About fourteen months after the first experimental work was initiated, full-scale production of glass of admirable quality commenced and has continued uninterruptedly, so that Australia is now not only completely independent of external supplies but is even exporting optical glass to other countries. This achievement has been due to close co-operation between the Chemistry Department of the University of Melbourne and the technical staff and facilities of Messrs. Australian Consolidated Industries Ltd., to which organization the actual production of the glass was entrusted. It is also a pleasure to record the very willing assistance received from the staff of the National Bureau of Standards, Washington, who placed freely at our disposal their extensive knowledge of technical details, thereby saving us much valuable time.

The original programme called for the production of six standard types of optical glass; this number was afterwards reduced to four which are now in production, but all six were made successfully in the laboratory. There were two main problems: (a) suitable raw materials for the glasses; and (b) suitable fire-clays for the pots. Fortunately, excellent sand was available in quantity, being in regular use for making flint glass for table ware. This sand contains less than 0·01 per cent iron oxides and the optical glasses made from it have proved to be almost ideal in regard to freedom from colour and turbidity. Other raw materials of high purity were soon located and removed further anxiety in this respect. The main experimental investigation was therefore directed to the selection of suitable pot-clays. About eighty specimens from various parts of Australia were examined as to refractoriness under load, shrinkage, chemical composition, especially iron and titanium content, texture and workability. From these about ten clays were selected for further trial; these were suitably blended and fashioned into small open pots holding about 2 lb. of glass each. These pots were fired in a small gas furnace and the glass batch introduced through a silica tube into the pot at 1,400° C. until the glass was in quiet fusion. After stirring with a silica rod, the pot was heated at a steady temperature (usually 1,450° C.) for 12 hours, cooled down, cracked open and the glass examined for pot contamination.

In such small pots, it was, of course, impossible to make optically homogeneous glass, but the resistance of the clays to glass attack and their general quality under the severe test conditions could be readily ascertained. It was felt that the results of these tests could be applied to the construction of suitable large pots with safety, owing to the better volume-surface ratio in the latter and the lower and more controllable temperature to which they would be exposed. These expectations were realized, and it was also found possible to slip-cast the large pots and dry them ready for the pot arch in about six weeks. As these pots can be raised to the temperature of the melting furnace in 4½ days, a great saving in time is thereby accomplished.

The pot-making and optical glass annexes have been very simply constructed to facilitate handling and reduce labour to a minimum. The capacity of the former is amply sufficient to maintain a supply of pots for a one-day melting schedule for the glass, which in turn reduces shift problems and operating costs, while the pot-handling and the stirring equipment is simple and efficient. After inspection of the chunks of glass from the pot, they are softened and moulded into the required blanks in special steel moulds which produce a very clean product, thus requiring only small tolerances. These blanks are then annealed in electric annealers before being finally inspected.

A most satisfactory feature of the production has been the high yield per pot (55–60 per cent) of usable glass, most of it of very high quality. For example, measurements by the National Standards Laboratory of Australia have shown quite remarkable constancy in optical properties of the glass from various parts of an individual pot, combined with very satisfactory freedom from striation or other blemish. Tests on eight consecutive melts of borosilicate crown yielded a mean refractive index (Na) of 1·5100 ± 0·00023 and barely detectable differences in dispersion. Indeed, the glasses now being produced fall in properties well within the tolerances set by the Australian Optical Munitions Panel, and ensure, therefore, an abundant supply of excellent material for munitions purposes.

OBITUARIES

The Very Rev. Sir George Adam Smith, F.B.A.

THE VERY REV. SIR GEORGE ADAM SMITH died on March 3 at his residence, Sweethillocks, Balerno, Midlothian, in his eighty-sixth year. A native of Calcutta, he was son of George Smith, who had a high reputation not only as a journalist but also as a biographer of missionaries. The young George was brought to Edinburgh, where he was educated at the Royal High School and the University. His university period does not seem to have been marked by any special distinction in examinations, though I fancy he must have taken a high place in the English class, if we are to judge by his writings. But he made valuable friendships there with such men as Henry Drummond, R. W. Barbour, Thomas Shaw (afterwards Lord Craigmyle) and R. B. Haldane, the great philosopher and war minister. His attachment to Edinburgh remained deep to the last. As a member of the Free Church of Scotland, he naturally proceeded to New College for his divinity course, when he had decided on the ministry as his life's work.

These were days of high tension in ecclesiastical circles. Smith must long have felt a strong attraction to the Old Testament, which contact with the celebrated teacher, 'Rabbi' A. B. Davidson, could only tend to accentuate. At that time the name of William Robertson Smith was on every lip in Scotland. He had imbibed in Germany what were then advanced views on the sources of the Pentateuch and on other Old Testament problems, and had set them forth in notable articles in the *Encyclopædia Britannica*. As a result he was tried for heresy by the General Assembly, and was ejected from his chair at the Aberdeen College.

George Smith, who had studied at two German universities after his Edinburgh courses were finished, and had afterwards travelled in Egypt and Syria, became an assistant minister at Brechin, but was soon appointed to carry on the work of Robertson Smith's chair, and thus had his introduction to Aberdeen, where he was destined to spend a large portion of his life. The extension of the city westwards had led to the erection of a very handsome church at the point known as Queen's Cross. The Aberdonians of those days were famous as church-goers and sermon tasters, and the members of this church were early convinced that Smith, who had been heard in various pulpits, must become their minister. He remained in this position for ten years, 1882–92, and built up a lasting reputation as a brilliant preacher and faithful minister.

Smith was able in the course of that period again to travel in Syria and east of Jordan, and subsequent visits served to confirm a knowledge of that region such as very few Hebraists in our time have attained. Not only was he the best interpreter of the Old Testament prophets to his generation, but also he had a very keen eye for the influence of geography on history. His "The Book of Isaiah" (1888–90), which grew in part out of his sermons at Aberdeen, made him known throughout English-speaking lands. The year 1896 was marked by the first of a number of visits to the United States, where as lecturer, preacher and public speaker he gained a high reputation. Perhaps the most notable of his works is his "Historical Geography of the Holy Land" which, originally published in 1894, reached a twenty-sixth edition in 1935. He set an example to other scholars by issuing revised editions of several of his works, including this, some years before his death.

On appointment to the chair of Old Testament languages, literature and theology in the United Free Church College at Glasgow, Smith had left Aberdeen in 1892. In Glasgow he found time to take an interest in social problems, such as the life of the very poor in that vast city. When in 1909 the Crown appointed him to succeed Dr. John Marshall Lang as principal of the University of Aberdeen, there was a good deal of ill-feeling in Church of Scotland circles, but this was soon lived down, especially as no one on the United Free Church side rejoiced more in the re-united Church of Scotland than Smith did. (He had been Moderator of the United Free Church Assembly in 1916–17.) It is perhaps too soon to sum up his twenty-eight years principalship, but two things may, I think, be said, that the relations between University and City were cemented as never before, and that the power of the University Court was increased at the expense of the Senatus.

If Smith was a brilliantly successful man, he did not escape sorrow. The first and second of his three sons were killed in the War of 1914–18, and his second daughter died a few weeks before her father. He was a man of deep feeling and ceaseless activity. His life was as full perhaps as that of any academic person of his time. It merits and will no doubt receive an adequate biography. His portrait was painted at least three times, by Aiken, Orpen and Souter: the second is at King's College, Aberdeen, the third at Trinity Hall, Aberdeen. A. Souter.

Lieut.-Commander L. C. Bernacchi

Lieut.-Commander Louis Charles Bernacchi was born in 1876 in Tasmania, and spent his early years in Melbourne, where his father was astronomer to the State Government. The call of physics, and especially of magnetism, therefore came naturally to him, and at the age of twenty-two he went as physicist to the first expedition which ever wintered on the Antarctic continent. This was the Newnes Expedition of 1898–99, led by Borchgrevink, which wintered at Cape Adare, within two hundred miles of the south magnetic pole.

Bernacchi had only just returned from that journey when he joined the National Antarctic Expedition of 1901–4 under Captain Scott, and he was the author of several physical reports after its return. Magnetism is often thought to be one of the more sedentary sciences, but it took Bernacchi on a thirty-day sledge trip on very short rations out over the featureless Ross Barrier with a Barrow dip circle with which he took observations each night after man-hauling all day. Scott's narrative in fact nearly always associates the word "energy" with Bernacchi's name. Two magnetic huts which he built at Hut Point were, ten years later, to prove a godsend to a marooned party of men who found building material from them, bricks for blubber stoves, lamps and copper sheets and brass tubes, so that his name became a household word for anyone seeking such things. There was even cement in not too desperate a condition.

Returned from the south, Bernacchi travelled again, this time in tropical regions, but a few years later found him forsaking physics and the wilds for a life in the City of London. But his interest in polar work never diminished, and in one way or another he was associated with most of the later expeditions.

His energy and almost restless interests took him into many fields—economics, civics and politics—as well as leading him to serve on many committees and councils.

After the War of 1914–18, in which he served in a special branch of the R.N.V.R., his polar interests crystallized in a very practical form by his taking a leading part in the formation of the Antarctic Club, of which he was the senior member. It is the pleasant custom of that Club at its annual dinner for the president to take wine in turn with the representatives of each successive expedition to the south. No member of the Club is likely to forget the sturdy figure with its genial smile which year after year rose to the first call of the evening: "The President wishes to take wine with the member of the Southern Cross Expedition of 1899, Commander Bernacchi".

Frank Debenham.

Dr. Adrien Loir, M.B.E.

A direct link with the life and work of Louis Pasteur was severed by the death in Paris of his nephew, Dr. Adrien Loir, on December 16, soon after he had entered his eightieth year. His father, who was professor of chemistry at the University of Lyons, trained him in laboratory technique so that he might help Pasteur in his experimental work. The youth was fortunate in having been chosen by his uncle to accompany him in September 1882 to Bollene in the Department of Vaucluse, where Pasteur and Thuillier, during the next two and a half months, investigated an outbreak of *rouget* (swine erysipelas). During 1882–88 Adrien Loir assisted Pasteur in the little laboratory in the Rue d'Ulm. This was a notable period in the active life of Pasteur, for it included his researches into the treatment of hydrophobia in man and the prevention of anthrax in domesticated animals.

Dr. Loir helped to establish a number of Pasteur institutes in various parts of the world: in St. Petersburg in 1886; in Sydney in 1889; and in 1893 in Tunis, where he remained as director for nine years. He held a chair in the University of Montreal during a two-year stay in Canada, and he then returned to France on his appointment in 1909 as medical officer of health of Havre; he continued in this post until his retirement in 1939.

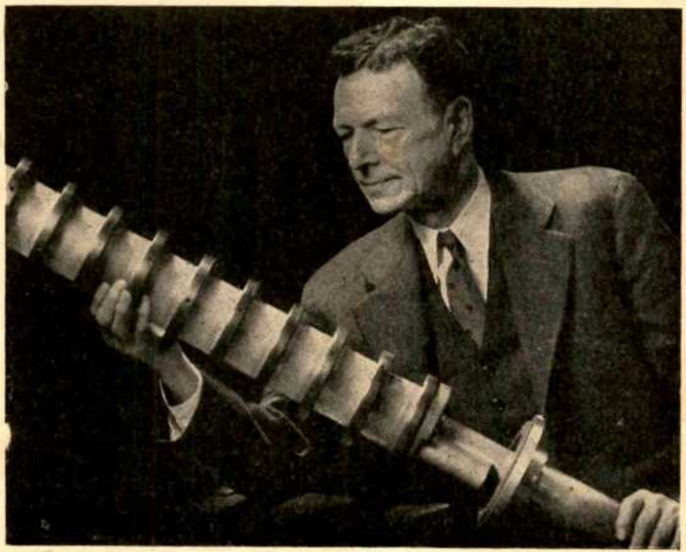
Loir published papers on public health problems such as infant mortality and the prevention of typhoid fever; and he had an international reputation for his knowledge of methods for reducing the rat population in seaports. He was hopeful that good results might be obtained by the use of special breeds of rat-catching cats, but later he realized that the prevention of rat infestation and indirectly of the spread of plague infection consists essentially in applying general hygienic measures and, in particular, in making it impossible for rats to find food and shelter.

Dr. Loir proved to be so helpful to the British authorities in the War of 1914–18, when Havre was an important base for British troops, that he received the award of the M.B.E. for his services. Many honours and distinctions, including the degree of doctor of laws of the University of Glasgow, were bestowed upon him during his varied and useful career.

NEWS and VIEWS

Dr. W. D. Coolidge : Duddell Medallist

THE eighteenth Duddell Medal of the Physical Society has been awarded to Dr. William David Coolidge in recognition of his pioneer work in the production of ductile tungsten and, more especially, of his invention and subsequent development of the hot-cathode high-vacuum X-ray tube which is everywhere known by his name. The medal was formally presented to him on May 1 by Viscount Halifax, H.M. Ambassador in Washington, at a dinner of the American Physical Society at Baltimore. Born in 1873, Coolidge began life on a farm in Massachusetts. He found means of entering the Massachusetts Institute of Technology, where he graduated in 1896 and remained until 1905, except for a short period at Leipzig. He then joined the staff of the Research Laboratory of the G.E.C., Schenectady, N.Y., becoming assistant director in 1908, associate director in 1932, and finally director of research and vice-president of the Company in 1940. He has been widely honoured both in his own country and in Europe: of several universities he has received honorary degrees, and of many learned societies he is an honorary member or a medallist; in Great Britain he has received the Hughes Medal (1927) of the Royal Society and the Faraday Medal (1939) of the Institution of Electrical Engineers.



DR. W. D. COOLIDGE

The Coolidge tube is described in his original paper as "an X-ray tube with pure electron discharge." Unlike the older cold-cathode gas tubes, it affords exact control of both intensity and 'hardness' of the radiation through the adjustments of the filament current and the accelerating potential difference, and operates continuously without change in either respect. During the War of 1914–18, Dr. Coolidge produced complete X-ray field installations including specially designed tubes of large thermal capacity, and later he developed self-contained oil-immersed outfits, which became widely applied in dentistry and in industrial laboratories on account of their easy manipulation. For high voltages he developed a multi-section tube with intermediate tubular electrodes for step-by-step acceleration of the electrons; in the accompanying photograph Dr. Coolidge is holding a million-volt tube of this type. Such tubes have been used for deep therapy under closely controlled conditions, and for the examination of materials in industry. In other tubes of this type the electron beam is made to emerge through a 'window' in the tube, and its effects have been investigated.

Ministry of Works and Planning

THE Ministry of Works and Planning Bill, which received its second reading in the House of Commons on April 29, while recognizing the principle that private profit must not be allowed to regulate the surroundings and conditions of our life after the War, is, as the Paymaster-General admitted in his speech, a very small step towards the solution of problems of planning. The purpose of the Bill is to provide for the transfer to the Minister of Works and Planning of all the existing functions of the Commissioners of Works and the Commissioners of Public Works in Ireland, and of the existing town and country planning functions of the Ministry of Health (but not its housing powers). The precise relations of the Minister of Works and Planning and the Paymaster-General are obscure, nor is it clear how far the transfer of powers goes. The Bill is, however, a step forward towards the creation of the central authority for planning in Great Britain, put forward by the Uthwatt Committee in its first recommendations.

British Reconstruction Associations

A BROADSHEET entitled "British Reconstruction Agencies" recently issued by P E P (Political and Economic Planning) affords a valuable supplement to the summary of research activities in this field included in the "Destruction and Reconstruction" issue of the *Architectural Review* of last July. Apart from its handier form for reference, the broadsheet includes, in addition to particulars of official agencies for physical reconstruction and of committees and voluntary organizations concerned with particular aspects, notes on the Inter-Allied Relief Bureau groups working for the Allied Governments, and organizations for the study of international reconstruction. An introductory note stresses the importance of a bold reconstruction policy as an essential part of the War effort. This was emphasized by Sir Stafford Cripps early in March and is one of the keynotes of an admirable report "The Old World and the New Society", issued by the Labour Party last month. The greatest weakness of British studies on reconstruction at present, says the broadsheet, is that they are not clearly enough linked with the War effort, and while many regard 1942 as the decisive year of this War, fewer seem aware that it may equally be the decisive year for the peace. Both may be lost if we cannot now convert the fight of the United Nations into a genuine crusade for a supreme moral principle and for the building of a people's civilization out of the civilization of a privileged few. Great Britain in particular needs to grasp this relationship of reconstruction policy to the War effort, and to recognize that the vision of a new order at home and abroad is an indispensable weapon both in the waging of a war and in the winning of a peace.

The United States and the War

Written before the United States entered the War "The Arsenal of Democracy" (Oxford Pamphlets on World Affairs, No. 53. London: Oxford University Press. 4*d*. net) still gives a pertinent account of the economic contribution of the United States towards the defeat of the Axis powers. After describing the movement of American opinion towards aid to Britain and her Allies, and the successive stages of American action before and after the passage of the Lease-Lend Act, Mr. A. J. Brown discusses the war-potential of the United States and its mobilization. His pamphlet gives a lucid account of the problems of the transfer of a peace-time economy to a war-footing and, if supplemented by current articles of the type appearing in recent issues of *Fortune*, should enable the reader to assess reasonably the significance of the bottlenecks of machine tools, skilled labour and raw materials. The labour and administrative problems are clearly displayed and the American contribution in ship-building, aircraft production and other supplies is fairly indicated; there is a useful appraisal of the relative strength of Great Britain, the United States and the U.S.S.R. in comparison with the Axis powers and with special reference to the time factor.

Academy of Sciences of the U.S.S.R.

A general meeting of members and corresponding members of the Soviet Academy of Sciences was held in Sverdlovsk, in the Urals, during May 2–7, to discuss the plan of scientific research work for 1942. The following papers were read: "Urgent Tasks of Science in Mobilizing the Resources of the Eastern Districts of the U.S.S.R. for the Needs of Defence", by Profs. Komarov and Bardin; "The Tasks of Social Science in the War", by Prof. Alexandrov; "Some Fundamental Problems of Agricultural Science", by Prof. Lyssenko; "Physics and the War", by Prof. Joffe; "Biology and War", by Prof. Orbeli; "The Teutonic Order, its Early Successes and Final Defeat", by Prof. Tarle; "Historic Documents of the Red Patriotic War", by Minsky. The meeting also discussed the adjustment of the Academy's work in accordance with the needs of the War.

Medical Progress in China

In a recent lecture published in the *Asiatic Review* of April, Dr. W. H. Woo gives an interesting survey of medical progress in China from the earliest times. The origin of native medicine can be traced back to the earliest Chinese emperors, who flourished three or four thousand years ago. So early as the Chou dynasty, about 700 B.C., medicine had reached a high degree of development, and four kinds of medical man—physician, surgeon, dietician and veterinary surgeon—were distinguished. Afterwards, one of the most notable events in the history of Chinese medicine was the publication by Li Shee Chin about A.D. 1578 of a materia medica consisting of fifty-two volumes and containing not only herbs but also drugs of animal and mineral origin as well. A new medicine was introduced in 1835, being due chiefly to Dr. Parker, who founded the first hospital in China, but it was not until three quarters of a century later that Sun Yat Sen, the founder of the Chinese Republic and himself a medical man, placed medical services on a proper footing.

In 1927 a Ministry of Health was founded in China to reorganize public health centres and reform medical education. In spite of an energetic campaign against disease, the death-rate from various causes in China is still very high. According to the latest annual statistics, the infantile mortality in China is 200 per thousand, and the maternal mortality 15 per 1,000, as compared with 53 per 1,000 and 4 per 1,000 respectively in Great Britain, and tuberculosis kills 5 out of every 1,000 Chinese, while in Great Britain the proportion is ten times lower. An active campaign has been undertaken against opium smoking, and this evil would doubtless have been eradicated but for the Japanese, who encouraged the habit and distributed opium free in occupied territory. In pre-war days, medical schools in China numbered about thirty-six, but many of them have since suffered from depletion of staff and loss of laboratory equipment, to remedy which the present policy of the Ministry of Education is to confine medical education to centres in Free China.

Gold Coast Timbers

All over the Empire, wherever forests at all accessible exist, the same formula is heard expressed: "War-time conditions have brought about an increased demand for timber both locally and for export"; and the demands of the fighting forces are to a large extent responsible for this increased demand. On several occasions allusion has been made to this factor in Nature. There may occasionally be an asset to set against these often unsupervised extra fellings, one of which is mentioned in a publication of the Forestry Department of the Gold Coast entitled "Gold Coast Timbers" (Govt. Printers, Accra, 1941), issued under the name of the Chief Conservator of Forests, who had the assistance of officers of the Department in its compilation. As was the case during the War of 1914–18, especially in India and Burma, the great demands by the Army and, in the present War, largely increased demands for commercial war production, have necessitated a larger call on the tropical forests and the bringing into utilization of timbers for which there was no commercial demand in peace-time. As the author says of the Gold Coast, timber is required for many and varied purposes, and species formerly but little used have come into prominence.

It was in view of this extra demand that the present small monograph was prepared. It only purports to give a summary of existing information about some of the more important Gold Coast timbers, forty-four in number; other species in the forests not mentioned may prove as useful, it is said, in the future, even if not more useful, than some of those here dealt with. There are some 20,000 square miles of high forest and double that number of savannah forest. Some 1–1½ million acres of the high forest are classed as at present accessible. On the subject of distribution and frequency of species, enumeration surveys have been carried out to a certain degree, but it is emphasized that average figures only have been obtainable from them. This is, however, quite in keeping with the ordinary first attempts to obtain some knowledge of the stocking in the tropical forest. The suggested classification of durability and impregnation susceptibility appear to be somewhat clumsy and capable of simplification. A summary of the uses of local timbers is given. The little monograph should prove of use both to forest officer and timber buyer; and may even ensure some measure of control over the all too common unsupervised fellings in tropical forests, which have been taking place on an increased scale.

The Imperial Forestry Institute

In the seventeenth annual report, for 1940–41, of the Imperial Forestry Institute (Oxford, The Holywell Press, Ltd., 1941) it is stated that the year was the first under the new organization, one result of which is to amalgamate the Oxford School of Forestry with the Institute. The interruptions of leave and so forth naturally interfered with Colonial forest officers taking refresher courses at the Institute. As has been the case with other forestry schools, practical forestry courses had to be confined to Great Britain. The professor of forestry, Prof. H. G. Champion, was fortunate in being able to retain a certain staff at the Institute. As a consequence some degree of investigation and experimental research work was continued in sylviculture, mensuration and management, soil science (in which the valuable co-operation of Dr. M. C. Rayner of Bedford College, London, was afforded), tropical forest botany and fruit pathology.

Economy of Tin in Bearings

Since the change to Japanese control of the tin-producing regions in south-eastern Asia, the sources of about two-thirds of their supplies have been lost to the Allies. In an attempt to make this good, the Ministry of Supply has just issued a pamphlet on modifications recommended in bearing-metal practice. More than 2,000 tons of tin are used annually in Great Britain in bearing-metals, and the new suggestions, if loyally adopted, would, it is estimated, ensure a saving of 65 per cent, equal to the entire output of the Cornish mines last year. This pamphlet is available from the Non-Ferrous Metals Control, Grand Hotel, Rugby, or the Tin Research Institute, Fraser Road, Greenford, Middlesex. The white bearing-metals have been divided into four groups with 80–92, 68–75, 7–12 and 0–5 per cent of tin respectively. Alloys with 12–68 per cent of tin have very rightly been omitted entirely, as suitable alloys for practically any purpose can be found in the compositions still retained, modified, if necessary, by other additions. A long list of typical bearings is given with the class of alloy suitable for each. Alloys falling outside these groups may be used only with the approval of the Non-Ferrous Metals Control.

A further appreciable saving may be made by reducing the thickness of white metal linings, a practice which has been steadily growing for some years. As a result, especially in the automobile industry, it has been found that the thinner linings can often carry heavier loads with an increased factor of safety. Other suggestions for economy include careful segregation and collection of scrap, the use of steel bushes lined with bronze instead of solid bronze ones, and the substitution, for most purposes, of an alloy containing 85 copper, 5 tin, 5 lead, and 5 zinc for Admiralty gunmetal.

The U.S. National Academy and Calendar Reform

A poll of the U.S. National Academy of Sciences indicates a three-to-one preponderance of opinion in favour of a calendar reform which would 'even up' the lengths of the months, giving each twenty-six working days and having each month begin on a Sunday. The ballot was conducted by Prof. W. E. Castle, of the University of California, Berkeley. He received responses from 168 of them, or more than half the membership of the Academy. Of those answering, 76 per cent favoured the change, 10 per cent opposed, and 14 per cent were undecided. Of those who favoured the change, 58 per cent wanted it initiated in 1945, which is the next year that begins on a Sunday; 42 per cent were against this unless the War ends soon enough.

Earthquakes in the Pacific

The United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association has found the epicentres of two recent earthquakes. The first, on March 1, 1942, took place at 9h. 52·0 m. U.T. The tentative epicentre, calculated from instrumental recordings at eight observatories, was latitude 13° N., longitude 91° W., which is in the Pacific Ocean, south of San José in Guatemala (Central America).

The second shock, on March 5, 1942, at 19h. 48·2 m. U.T., had its provisional epicentre at latitude 48° S., longitude 98° W., which is in the Pacific Ocean to the west of southern Chile. The focus of this latter shock is estimated to have been at a depth of some 250–300 km., so that it might be termed an 'intermediate' shock. Earthquake shocks have been known to occur down to depths of 700 km. Both the above earthquakes occurred in regions known to be liable to earthquakes.

Demographic Census of Rio de Janeiro

The last census of Brazil showed that on September 1, 1940, Rio de Janeiro had 1,781,567 inhabitants (*J. Amer. Med. Assoc.*, Feb. 14). The decline of births was illustrated by the fact that whereas in the period 1921–1930 the births numbered 344,921, in the period 1931–1940 only 321,976 births were registered, although there was an increase in the population. In the first period there were 248,964 deaths, and in the second period 274,233. This increase, however, was not in proportion to the growth of the population. In the same periods the marriages numbered 80,545 and 106,112 respectively, though there was a decrease in the birth-rate. The population of the capitals of the Brazilian States was 5,661,091 in 1940, or 13·6 per cent of the population of the whole country. In 1920 the figure was only 8·6 per cent of the whole nation.

Institute of Fuel: Melchett Medallist

The Melchett Medal for 1942 of the Institute of Fuel has been awarded to Dr. Arno Carl Fieldner, the head of the Technologic Branch of the Bureau of Mines, Washington, for outstanding work carried out by him and under his supervision in connexion with fuel. The Melchett Medal was founded in 1930 by the first Lord Melchett, and has been presented to seven Englishmen, one American, one Frenchman, and three Germans.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

The Social Sciences

An editorial appeared in *The Times* of March 28 under the heading "Social Surveys", accompanied on the same day by a special article entitled "War-time Social Surveys". It was there suggested that a Social Science Research Council might be set up as a guide to the Government.

In view of recent discussions that have taken place about the establishment of such a Council, certain suggestions there put forward by the writer of the special article seem to call for comment.

Some of the most fruitful experiments in social life as well as in the practice of government spring out of the needs of war-time. No one more than myself will praise the "utilitarian objective" in science. (Incidentally, I note that the word 'science' has dropped out of "Social Science Research Council" and the word "National" has been inserted; surely a significant change.) No one will despise £40,000 annually coming from the Government "for the Advancement of Science". But I do sincerely trust that any Social Science Research Council that may be set up after or during this War will not be a Government-controlled body, but an academic body.

The Economic Advisory Council or its successor is appropriate to meet, under Cabinet control, the Cabinet's need. Politicians and Civil Servants are not generically inspired by the pure desire to know; and the sharp distinction between science and 'business of State', menaced in every direction of modern life, is far more basic in the social than in the physical or medical sciences. This does not mean that an academic Social Science Research Council, enjoying the same independence as the Royal Society, cannot be of immense aid to a Government that refers problems to it for research, in just the same fashion as its counterpart, the American Social Science Research Council has been.

George Catlin.

The Solar Corona

The difficulties which have so far been experienced in working out a physical theory of the solar corona (*vide* Rosseland, "Theoretical Astrophysics", Chap. 14) have apparently been increased by the discovery of Grotrian and Edlén that many of these lines are due to forbidden transitions of highly stripped atoms of iron and nickel having the constitution $3\,p^x$ ($x = 1$ to 5), and to calcium atoms having the constitution $2\,p^x$; thus the line 5303 is produced by an iron ion which has lost as many as thirteen electrons. After learning of this extraordinary discovery from an article by Prof. H. N. Russell in the *Scientific American* of August, 1941, I undertook a critical examination of the available spectroscopic data, and can confirm that the claim is a sound one.

Prof. Russell has pointed out that the solar corona apparently shows a predominance of the very same elements which are found prominently in iron-meteors, but to me the coincidence appears to be only fortuitous. From extant observations we can draw a fairly safe conclusion that the lines cannot be due to large-scale meteor flashes; but the stripped atoms responsible for the lines are streaming outwards with high velocities. This conclusion follows (1) from the work of Lyot[1] (1937) that the breadth of the coronal lines, which is unusually large for a temperature of 6,000°, *increases* as we approach the solar limb; (2) from the work of Waldemeier[2] (1938), in which it is shown that the great breadth of the coronal lines may be explained as being due to radial streaming of particles, and the greater the breadth, the greater is the velocity. In the inner corona, the velocity is reduced to nearly 60 km./sec., but it must be much larger in the chromosphere, and in the reversing layer, where as will be shown presently, the particles originate.

If these conclusions are granted, we have next to find out what physical processes give rise to such highly stripped atoms and send them through the solar envelope with such tremendous velocities. It is obvious that we have to exclude thermal or photo-electric ionization and generally all extra-nuclear processes.

The only plausible hypothesis appears to be that these highly stripped atoms are produced in a nuclear reaction, analogous to uranium fission, occurring somewhere inside the reversing layer. It is known from investigations on uranium fission that the fission fragments separate from each other with energies of the order of 80 Mev. corresponding to a velocity of 6–8 cf, where c is the velocity of light, f is the Sommerfeld fine-structure constant (cf is the velocity of the electron in the first H-orbit). These fission fragments are known from experiments by Böggild, Lauritsen and others[3] (1942) at Prof. Bohr's laboratory at Copenhagen to be endowed with a high net positive charge at the moment of their production; in fact, they are found to have lost all those outer electrons the orbital velocities of which are inferior to their own velocity of separation (6–8 cf). An iron atom which retains only 10 electrons, namely, Fe^{+} $1s^2 .\ 2s^2 .\ 2p^6$, . . . should have a velocityof 6·5 cf at the moment of its production and hence its energy should be 60 Mev. There is one difficulty in this hypothesis. So far only ^{238}U, ^{235}U, ^{232}Th and ^{231}Pa have been shown to be capable of fission (Bohr and Wheeler[4], 1939), and experimentally fission into two fragments only has so far been demonstrated. But this difficulty is not insuperable; on energetic grounds, fission into a larger number of fractions, say three or four, is possible. As for the presence of the fission elements in the sun, their spectra is so complex that no serious attempt at identification has yet been undertaken.

In any event, the presence of Fe^{+13} or Ni^{+15} moving through the solar envelope with large velocities is a demonstrated fact, and one can calculate the range and electron exchange of these particles. If we make the reasonable hypothesis that the iron ions start at the moment of their production as Fe^{+16} $1s^2 .\ 2s^2 .\ 2p^6$ they would have an initial velocity of 6·5 cf. Their career through the solar atmosphere is analogous to that of α-particles, or better of fission fragments through the cloud chamber. They would be losing energy all the way because they ionize the solar atoms with which they come into contact according to the process known as ionization by collision. The solar atoms from which α-rays are expelled may b supposed to be mostly hydrogen atoms, and on reasonable assumptions, the range comes to abou 10^{21} hydrogen atoms. The particles must, therefore originate inside the reversing layer.

Further, there will be a lively interchange of electrons between the stripped ions and the solar atoms according to the processes described by Jacobsen[5] (1930), and Kramers and Brinkmann[6] (1930). As the velocity decreases, more and more electrons will be acquired, in the normal or metastable states, and ultimately, the ion emerges in the inner corona where alone it has a chance of being observed as an ion with a $3p^x$-structure, with much-reduced velocities (60 km. per sec.).

It is interesting in this connexion to recall the following intuitive remarks of the late Lord Rutherford: "In the furnace of the Sun and other hot stars, the electrons, protons, neutrons, and atoms present must be endowed with high average velocities owing to thermal agitation. It is thus to be expected that the processes both of disintegration and aggregation of nuclei, such as are observed in the laboratory, should be operative on a vast scale for all nuclei, and that a kind of equilibrium should be set up between these two opposing agencies of dissociation and association for each type of atomic nucleus."

The nuclear reaction envisaged here is of a type which was not suspected when Lord Rutherford wrote the above passage. But it is quite possible that nuclear reactions of the type contemplated by Lord Rutherford are also constantly taking place, even on the surface of stars. The occurrence of the He^+-line, 4686, in the lower chromosphere, and of He-lines in the upper chromosphere, and the vanishing of the He-lines in the reversing layer have long remained unexplained puzzles (Perepelkin and Melnekov[7], 1935). For this case probably some kind of nuclear reaction which gives rise to α-particles is responsible; the α-particle in its passage through the solar envelope will first capture an electron, becoming He^+ in the normal or some excited state, then capture another electron, and become He in the normal or excited state. The process was first discovered in the cloud-chamber studies of α-rays by Henderson and Rutherford[8], who showed experimentally that during the last centimetre of its path, the α-particle may gain an electron and then again lose it nearly a thousand times. During the last few millimetres, He^+ may gain and lose electrons a large number of times.

The outer corona is now believed to consist entirely of electrons, but difficulty has been found in tracing the origin of these electrons. They are probably the δ-rays expelled from solar atoms by the highly-stripped iron or nickel ions in the upper chromosphere.

A complete physical theory of the solar corona on the above lines has been worked out and is in process of publication in the *Proceedings of the National Institute of Sciences of India*.

If the consideration presented here prove to be correct, the occurrence of coronal lines is a fingerpost showing that nuclear reactions are taking place even on the gaseous envelope of the sun, and possibly also of stars, and may in some cases influence observable stellar phenomena to a not inconsiderable extent.

History of the British Thermal Unit

A certain amount of interest appears to have arisen of late as to the history and definition of the British thermal unit. The position so far as we have been able to ascertain it is set out below, and it would seem that the British thermal unit under that name does not appear to have any very definite origin or legal definition.

In the early literature of Great Britain on the equivalence of work and heat, the unit of heat used was that which has since become known as the British thermal unit, but by Joule, Thomson, Rankine and others of that time it was simply referred to as a "heat unit". The Oxford Dictionary gives 1876 as the earliest date of use of the term British thermal unit. This occurs in "Catalogue of the Special Loan Collection of Scientific Apparatus at the South Kensington Museum, 1876" under item 1056. The complete entry (p. 273 of 3rd Edit.) is:

"*Hargreaves's Thermo-radiometer*, for measuring loss of heat by radiation from walls of furnaces, sides of steam boilers, etc.

"James Hargreaves.

"The silver-plated copper vessel is filled with water and enclosed in the case, the blackened face then being exposed for a given time (say, five minutes) to the radiating surface, a thermometer inserted in the neck of the vessel shows the elevation of temperature due to radiation. The heat is calculated as follows, either in calories or British thermal units, $\frac{Ws(T-t)}{am} = x$, where Ws = weight and average specific heat of vessel and contents, t = temperature of same before exposure, T, temperature of same after exposure, a = area of blackened face of vessel and m, time of exposure, whence may be calculated the amount of fuel necessary to replace the heat lost by radiation."

It would seem that this may have been a chance use of the term *British* thermal unit, as a means of distinction from the calorie, for reference to other works of about that time has shown that Lardner and Loewy's "Heat" (1877), p. 97, gives the unit, but no name, Cotterell in "The Steam Engine considered as a Heat Engine" (1878), p. 8, speaks of the quantity of heat being measured in thermal units. Prof. Everett in his "Units and Physical Constants" (1879) makes no mention of the British thermal unit, nor does it figure in the article on "Heat" contributed by Sir William Thomson to the 1880 edition of the "Encyclopædia Britannica". Furthermore, William Anderson, in his Howard lecture on "The Conversion of Heat into Useful Work" delivered on December 5, 1884, said: "I shall now explain that the quantity of heat or energy of molecular vibration which raises one pound of water 1° F. is called the British unit of heat" (*J. Soc. Arts*, 33, 565; 1885); on p. 576 he uses the abbreviation *u* for this unit.

In Prof. Jamieson's "Text Book of Steam and Steam Engines", 10th Edit. (1895), p. 32, however, one finds the definite statement: "The standard unit now adopted in this country is called the British Thermal Unit and is the quantity of heat required to raise 1 lb. of water by 1° F. when at its maximum density, i.e., from 39·1° to 40·1° F." (The temperature used by Joule when defining his "heat unit".)

Access to earlier editions of this work has not been possible, but it certainly appears that the British thermal unit as we know it to-day had become recognized by 1895. Writing on December 5 of that year, Prof. H. L. Callendar stated (British Association Report 1896, p. 159): "For steam engine work undoubtedly one of the most important units at present in use is the British thermal unit, or pound degree Fahrenheit."

The precise temperature at which the rise of 1° F. is to be measured does not appear to have been specified in any legal definition. The Gas Regulation Act, 1920, merely states: "The calorific value of gas means, for the purposes of this Act, the number of British thermal units (gross) produced by the combustion of one cubic foot of the gas measured at sixty degrees Fahrenheit under a pressure of thirty inches of mercury and saturated with water vapour."

The Act mentioned was based on recommendations of the Fuel Research Board, and the relevant reports have been published by the Department of Scientific and Industrial Research in a pamphlet entitled "The Therm" (H.M. Stationery Office, 1922). The therm is defined in the Act as 100,000 British Thermal Units.

Hyde and Mills in the introduction to their book "Gas Calorimetry" (1932), after referring to the Gas Regulation Act, 1920, go on to state: "The definition of a British Thermal Unit presents some difficulty since opinion differs as to the temperature at which it should be defined. For the purposes of this book, however, it is desirable that the values of a British Thermal Unit and a kilo-calorie should be easily convertible one to another. . . . The British Thermal Unit is therefore defined as the amount of heat required to raise the temperature of 1 lb. of water at 59° F. by 1° F."

In addition to this definition and that of Prof. Jamieson quoted earlier, other workers including Sir Alfred Ewing, "Dictionary of Applied Physics", 1, 922, and "Thermodynamics for Engineers", have defined the British Thermal Unit as 1/180 of the quantity of heat required to warm 1 pound of water from the melting point to the boiling point. This last is the definition given by the British Standards Institution for the mean British Thermal Unit in *B.S.* 205 (1926 and 1936), where the British Thermal Unit is defined as the quantity of heat required to raise the temperature of 1 lb. of water from 60° F. to 61° F.

The similar effect of variations in the specific heat of water on the value of the calorie was brought to the notice of the British Association in 1895 in a paper reproduced in the *Phil. Mag.* (40, 431; 1895). The suggestions made in this paper received considerable publicity and the correspondence was reproduced in the Report of the British Association for the following year.

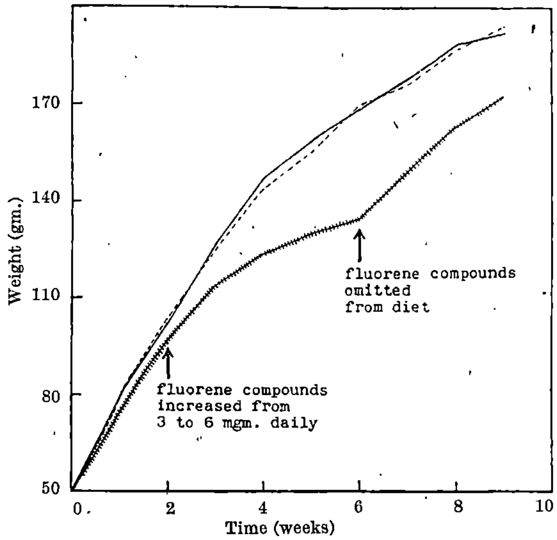
2-Aminofluorene as Growth Inhibitor for Bacteria and Rats

IN an effort to discover common mechanisms responsible for growth-inhibition of both tissue cells and bacteria, colloidal solutions of carcinogenic compounds (including 1-2-5-6 dibenzanthracene, 3-4 benzpyrene, methylcholanthrene, dimethyl yellow) have been tested systematically by us for possible bacteriostatic action. No very significant results have been obtained.

Recently, Wilson, DeEds and Cox[1] discovered the carcinogenic action of the insecticide, 2-acetyl aminofluorene. Its action is of peculiar interest since, when given orally, multiple tumours of different histological types developed in some rats. We found that 2-aminofluorene dissolved in nutrient broth had a bactericidal or strong bacteriostatic effect on certain bacteria and of these *Staphylococcus aureus* was chosen as the standard test organism. Since the corresponding acetyl compound has a considerable inhibitory effect on the growth-rate of rats, we decided to investigate related fluorene compounds in order to determine the effect of alterations in the chemical configuration on both the growth-rate of rats and that of the staphylococcus. We synthesized the following compounds: 2-aminofluorenone, 2-amin fluorenol, 9-aminofluorene and the correspondin acetyl compounds. The latter were used in rat-feedin tests and the compounds with a free amino group i the *in vitro* bacterial tests. 2-acetyl aminofluorene unsuitable for *in vitro* work owing to its poor sol bility in nutrient broth. Since, however, there is n reason to think that the acetyl group plays any pa in its specific *in vivo* action, it seemed justifiable t compare the action of the free amino compoun *in vitro* with that of the acetylated compounds *in viv* None of the compounds mentioned, with the e ception of 2-acetyl aminofluorene, had any significa growth-inhibiting action on rats (see accompanyi graph). The effect of the related compounds bacterial growth was similar except that 2-amin fluorenone had a definite bacteriostatic action, whi was, however, feeble compared with that of 2-amin fluorene (see accompanying table).



EFFECT OF FEEDING 2-ACETYL AMINOFLUORENE AND 2-ACETYL AMINOFLUORENONE ON GROWTH-RATE OF RATS.

Diet: whole milk powder (30 per cent) and bread; cod liver oil (0·2 ml. daily) and cabbage once a week. Full line, controls; broken line, feeding on 2-acetyl aminofluorene; crossed line, 2-acetyl aminofluorenone.

THE EFFECT OF 2-AMINOFLUORENE (1/10,000) AND 2-AMINOFLUORENO (1/10,000) ON THE GROWTH OF *Staphylococcus aureus*. INOCULU 10^6 COCCI/ML. MEDIUM

	Appearance of turbidity (hr.)	Degree of turbidity. Incident light absorbed (per cent) after (hr.) 13	16
Control culture	8	75	85
2-aminofluorenone	13	25	78
2-aminofluorene	45	0	0

The results indicate the importance of the presence of the two reacting hydrogen atoms in the 9-position, in combination with the amino group in the 2-position, in determining the growth-inhibiting and possibly the carcinogenic activity of 2-aminofluorene.

The possibility of studying the action of a chemical carcinogen by its effect on bacterial metabolism has obvious advantages in the analysis of the mechanism involved.

Time of Collapse of a Soap Bubble

A spherical soap bubble of radius R blown at the end of a uniform glass tube of radius a and length l will gradually deflate itself and disappear. Its time of collapse τ can be computed on the assumption that the gas inside the bubble of viscosity η passes out of the tube in streamline flow under the pressure excess in the bubble. In a spherical soap bubble of radius r, this pressure excess is $4T/r$, where T is the surface tension of the soap solution. Hence from a consideration of the viscous flow of a gas in a tube under a small pressure difference between its ends, it follows that,

$$-d\left(\frac{4}{3}\pi r^3\right) = \frac{\pi a^4}{8\eta l}\,\frac{4T}{r}\,dt\,;$$

whence

$$-\int_R^0 r^3 dr = \int_0^\tau \frac{Ta^4}{8\eta l}\,dt.$$

Hence $\dfrac{R^4}{\tau} = \dfrac{Ta^4}{2\eta l}$.

It has been found experimentally possible to blow spherical soap bubbles of more than 5 cm. diameter, the shape of which, in spite of gravity, can be considered to be spherical to a good approximation. When the bubbles are suitably blown, the vertical and horizontal diameters do not differ by more than a quarter per cent even in large bubbles of about 8 cm. diameter. The experimental results have confirmed the above relation, which therefore opens up a new method of estimating the surface tension of different soap solutions. Under suitable experimental conditions, a determination of the viscosities of certain gases *or* their effect on the surface tension of soap films is also rendered possible.

Experimental results will soon be published elsewhere.

Enzymatic Synthesis of Levan

Study of the formation of micro-organisms of polysaccharides from sucrose has been hampered by he absence of a satisfactory technique for the cell-ree isolation of the enzyme catalysts concerned[1]. This obstacle has now been removed. The separation of a dextran-synthesizing enzyme from *Leuconostoc mesenteroides* has been reported recently by Hehre[2]. t is the purpose of the present note to report the isolation from *Bacillus subtilis* and Aerobacter of an enzyme or enzymes which act on sucrose with formation of levan.

In sucrose-agar, colonies of *Bacillus subtilis* induce formation of levan to some distance from their site of growth[3]. When cell-free agar pieces from the vicinity of such *B. subtilis* colonies are aseptically removed to sterile sucrose solutions, they cause the gradual appearance in the fluid of a pronounced opalescence accompanying the formation of a polysaccharide which is identical in chemical and physical properties with levan. After 24 hours incubation, the amount of polysaccharide formed was considerable (300 mgm./per cent). When ground up in sucrose solution, a partial extraction of synthesizing enzyme from its agar matrix was obtained. This technique proved ill-suited, however, to the isolation of the synthesizing enzyme on a considerable scale.

A further and more convenient source of a levan-synthesizing enzyme was found in a levan-forming strain of Aerobacter. This organism, unlike most of the aerobic spore formers, is easily killed by narcotics. Cell-free autolysates prepared from an aqueous suspension of the cells by incubation with a little thymol in chloroform and subsequent centrifugation actively synthesized levan from sucrose (393 mgm. per cent in 40 hr.). On drying over Drierite in vacuum a stable water-soluble powder of considerable synthetic activity was obtained.

Control tests showed definitely that synthesis by the different enzyme preparations which have been described had occurred in the complete absence of living bacterial cells.

It seems reasonable to hope that with the aid of these enzyme preparations, new insight will be obtained into the sequence of reactions leading to levan formation. A full report on the properties and activity of the levan-synthesizing enzyme preparations will be presented elsewhere.

Meiosis in Drosophila

Up to now students of Drosophila have regarded meiosis in the male as almost inaccessible, and have, therefore, confined themselves to the genetical investigation of essentially cytological problems. This is due to the belief that meiosis was completed in the pupa and that only the actual spermiogenesis takes place in the adult.

I have worked principally with aceto-orcein smear preparations of testes of *D. subobscura*. Meiosis in this species starts in the fully grown larva and continues in waves throughout the whole of pupal and adult life at least up to a fortnight after eclosion. It subsides during periods of differentiation, for example, when the vasa deferentia begin to grow, and during periods of great stress, for example, on emergence, so that no divisions occur in young males up to two days of age.

In view of these facts Huettner's statement[1] that "adult males of *D. melanogaster* are useless for the study of meiosis" seemed improbable. I, therefore, made preparations from males of our Oregon line more than two days old. The testes exhibited all stages of spermatogenesis.

In the course of various experiments, I have been able to study mitosis and meiosis in *XY*, *XO*, and *XYY* adult males of *D. subobscura* and in *XY* males of *D. melanogaster*. Primary non-disjunction of the sex chromosomes was observed in both species.

It is hoped that by using adult Drosophila males, problems which demand the simultaneous classification of phenotype and chromosome type may now be tackled with greater ease.

Proteins Susceptible to Cold in Pathological Sera

In the blood of dogs infected with kala-azar, proteins are precipitated on cooling to room temperature (20° C.), or better still when allowed to stand in the ice-box (5° C.) overnight. This protein belongs to the pathologically increased euglobulin fraction. In twenty-one sera investigated (six cases) the cold fraction test was positive. In typical specimens, turbidity soon followed by precipitation sets in within a quarter of an hour of standing in the ice-box. The protein precipitated from kala-azar serum on cooling (cold fraction) is defined as the centrifugable protein fraction which precipitates after 24 hr. at 5° C., and is redissolved by warming to 37°–50° C. This cold fraction ranged between traces of turbidity which could not be determined quantitatively to maximal 3 gm. per 100 c.c. of serum. Typical cases gave tests as shown in the accompanying table:

Case	Total Prot.	Alb.	Glob.	Eu-glob.	Fibrin-ogen	Cold fract.	Dilution fract.*	Formol-gel
Dog 1	10·22	2·39	7·83	4·59	1·1	0·28	9·96	+
Dog 2	10·25	1·87	8·38	3·90	1·0	0·63	0·19	+
Dog 5	11·30	2·75	8·55	4·49	0·94	0·40	0·43	+
Dog 6	10·31	3·25	7·06	1·91	—	0·70	turbid	+
Human	6·06	1·72	4·34	1·81	—	+	+	+

* Dilution fraction: Dilution 1 : 30 with distilled water, centrifugable precipitate determined after 5 minutes standing at 20° C.

No clear-cut parallelism could be established between cold fraction Brahmachari and formol-gel tests. In Dog 1, identical cold fraction values were found simultaneously in serum (1·23 per cent) and exudate from artificial pleuritis (1·4 per cent).

The cold fraction is completely redissolved by warming to 37° C. In samples obtained from animals with particularly heavy infections, a relatively small fraction precipitates which is insoluble even at 60° C. If freshly drawn serum is allowed to stand at 37° C. for 24 hr. or at 60° C. for 30 minutes, precipitation in the cold occurs no longer. If the cold fraction is allowed to stand in its serum at 5° C. for a prolonged time, an increase or a decrease is observed; constant cold fraction values are scarcely ever obtained. A portion of this fraction does not redissolve on warming to temperatures up to 60° C. The cold fraction proved to be markedly labile.

In 0·9 per cent saline the cold fraction dissolves readily, and in this medium it is especially sensitive to temperature. At 70° C., irreversible heat precipitation occurs. The optimum *p*H, both of cold and heat precipitation, is at *p*H 5·7–6·2 (phosphate buffer). This fraction is particularly susceptible to diminution of salt concentration of the solvent.

Although the serum contained cold fraction, none was found in saline extracts obtained from tissues (lymph nodes, bone marrow, spleen, liver) of a dog suffering from kala-azar.

Hamsters infected with kala-azar showed no hyperproteinæmia and no abnormal proteins in the serum. The euglobulin values were normal. In dogs, visceral leishmaniasis is markedly chronic and is accompanied by a marked stimulation of the reticulo-endothelial cells; in hamsters infected with the strain of *L. donovani* used in these experiments, no such stimulation of the reticulo-endothelial system is produced.

We investigated five treated cases and one untreated case of human kala-azar. In all sera (eleven investigations) the cold fraction test was positive, but far less than in canine cases.

A large number of other pathological human sera was investigated as to the occurrence of the cold fraction. Only in a few cases of chronic infections (tuberculosis, malaria, osteomyelitis) was a weakly positive cold fraction test encountered. However, out of seven cases (twenty sera investigated) of endocarditis lenta, five cases gave positive cold fraction tests.

Precipitations which occur in plasma at low temperature are being investigated.

We are indebted for this material to Prof. S. Adler and Dr. J. Tchernomoretz, who kindly provided us with a steady supply of kala-azar dog serum.

Reversible Quenching by Oxygen of the Fluorescence of Polycyclic Hydrocarbons

In their recent letter in Nature[1], Drs. H. Weil-Malherbe and J. Weiss have overlooked the work of Bowen and Williams[2], in which the reversible quenching by oxygen of the fluorescence of solutions of fifteen aromatic hydrocarbons was measured. The fluorescence of naphthalene was found to be quenched at least as powerfully as the 3 : 4 benzpyrene to which attention is directed. The absolute fluorescence efficiencies of the hydrocarbon solutions were compared with the absolute rates of oxidation, and it was found that for naphthalene, anthracene, rubrene etc., the permanent oxidation was much less than corresponded to the quenching effect, proving tha a reversible dissociation of the quenching complex hydrocarbon - oxygen into the original molecule must occur. The general relations between fluorescence quenching and actual photo-oxidation by oxygen appeared to be of a very complex nature.

INFLUENCE OF SNOBBERY ON THE PRACTICE OF MEDICINE

THE lecture entitled "The Hand in Healing: a Study in Greek Medicine from Hippocrates to Ramazzini", delivered before the Royal Institution on December 4 by Prof. B. Farrington, professor of classics at University College, Swansea, has now been published by the Institution. In it Prof. Farrington discusses three topics: (1) the decline of anatomy and surgery after Galen; (2) the limitation of ancient medicine to the rich and the professional classes; (3) the invasion of medical science by *a priori* philosophical concepts. His object is to show that the decline in social status of the manual labourer (*a*) prevented the development of physics and chemistry, and (*b*) caused a gradual deterioration of anatomy and surgery. That chemistry and physics, in the modern sense, were practically unknown, that surgery after Galen was separated from medicine and rapidly declined, are admitted truths; the novelty in Farrington's paper is his finding the cause of these phenomena in the Greek dislike of what were called "banausic" occupations. This is a most ingenious suggestion, almost certainly containing an element of truth. The evidence, however, should be closely examined before the hypothesis is accepted; in a few places Prof. Farrington appears to have misunderstood it.

The meaning of "banausic occupations" raises a thorny question. "Banausia" seems to have been an Athenian conception, appreciated perhaps throughout Greece but to a less degree than at Athens. It signifies not so much a prejudice against manual work in itself—for full honour was given to painters, sculptors, soldiers and farmers—but only against wearying trades involving long hours in conditions that ruin the worker's physique and dull his intellect. Moderns feel a similar prejudice against certain monotonous operations in factories. Such pursuits *are* harmful; we are learning that "banausic" work should be done by machines rather than by men and women. The dislike of the Greeks was the result of a healthy instinct, but they are to be blamed because while accepting the facts they relegated "banausic" labour so far as possible to slaves, in order to have the leisure to live full lives as citizens. The first man to interest himself in occupational disease was apparently Paracelsus, who wrote a treatise on the ailments of miners. Be all this as it may, it would be difficult to show that medicine or even surgery was ever ranked among the "banausic" arts; by the time surgery came to be despised, the Greek ideals that gave rise to "banausia" had ceased to exist.

On p. 15 Prof. Farrington states that "the Hippocratic medicine was already (fifth century B.C.) limited in its application to a section of the people", that is, to the idle rich. Yet medical historians such as Rossignol (in 1858), Littré and Couch (in 1934) have pointed out that the patients of the Hippocratic clinical histories are for the most part humble folk, being indeed often slaves. This fact has to be reconciled with Plato's statement that for slaves there were slave doctors.

Prof. Farrington also takes the view that the long treatise "Regimen" was a medical text-book written by a typical Hippocratic physician for general use. This is extremely doubtful. It was probably the work of a professional trainer, who with a special purpose wrote for a special public—those who, fearing lest their work should be interrupted by a threatened illness, wished to 'nip it in the bud'. To call such people valetudinarians (p. 17) is perhaps unfair.

The intrusion of speculative philosophy into medicine, vigorously attacked by the author of "Ancient Medicine", appears, if we may judge from the subsequent literature, never to have had much effect on actual medical practice. Every art, in addition to the practical theory that explains and reinforces it, has beyond this a speculative background of theory pure and simple. This speculation has a useful part to play, the classic example being Manson's guess that mosquitoes are connected with malaria, a guess that led to the discoveries of Ross. In the infancy of science it tended to encroach upon practical theory, so that the author of "Ancient Medicine" felt bound to protest. Greek thought, in fact, was over-rich in this intelligent guesswork, throwing out suggestion after suggestion in wild profusion. We moderns on the other hand are prone to undervalue it, although every now and then a Jeans or an Eddington inspires us with restrained and beautiful speculation. On the whole, however, we confine such thought to fiction. We should not like to read H. G. Wells's fascinating theories in a text-book.

On p. 28 of Prof. Farrington's lecture we read: "almost two thousand years after Aristotle . . . was explicitly formulated . . . the belief in the existence of definite bodies capable of being isolated . . . and recombined into new compounds". The latter half of this sentence would surely be a good description of the atomistic hypothesis of Democritus!

Even if these criticisms be justified, Prof. Farrington's lecture is of great value, and must certainly be taken into account by historians of Greek thought.

THE GAS RESEARCH BOARD

THE Gas Research Board, which is supported by the Institution of Gas Engineers, the Society of British Gas Industries, and other bodies and individuals in the British gas industry, has recently issued its second report*. War-time conditions have prevented publication of some of the research done under its auspices and also the holding of the normal autumn research meeting.

The thirty-second report of the Refractory Materials Joint Committee*, which is also published, records, among other subjects, experiments on the materials used in the manufacture of firebacks for open coke fire-grates. Reference is made to the advantages in heating efficiency and performance of the use of the insulating refractory firebricks which have been so extensively developed in recent years.

Two reports, issued by the Gas Research Fellows for the year 1939–40 and 1941, deal with properties of Bunsen flames—in particular with flame ignition and propagation. There are two methods of measuring flame velocity: (*a*) the static method whereby propagation through a stationary explosive mixture is measured photographically; and (*b*) when the velocity is calculated from the form and size of the stationary inner cone of a Bunsen flame and the known rate of gas mixture fed to the burner. Hitherto results have shown great discordance, which has now been traced to the unjustified assumption that the inner 'cone' of a Bunsen flame is a true cone. It has now been shown that if the true area of the inner cone is measured and used in the calculation, then ignition velocities are obtained by this method which are independent of rate of mixture feed and burner size, depending only on working temperature and pressure. In other words, the ignition velocity so determined is a characteristic of the composition of the gas-air mixture. This should greatly facilitate the study of flame combustion.

---

* (1) Communication G.R.B. No. 4. Pp. 16. (2) Communication G.R.B. No. 5. Pp. 92. (London: Gas Research Board, 1941.)

It is often overlooked that the inner cone of a Bunsen flame does not touch the burner, from which it is separated by a 'gap' or 'dead space' in which the mixture is preheated to the temperature at which inflammation occurs. It appears that the size of the 'dead space' determines the possibility of 'lighting back', for when the diameter of the burner is reduced to twice the 'dead space', then the flame cannot pass down the tube. The influence of size of tube and hole in stopping the travel of flame is well known and usually ascribed to the cooling, but it now appears to be essentially a characteristic of the gas.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk are open to the public*)

Tuesday, May 12

Chadwick Public Lecture (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 2.30 p.m. —Dr. J. Alison Glover: "The School Medical Service in War-time".*

Illuminating Engineering Society (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. G. H. Wilson: "Street Lighting: Past, Present and Future".

Wednesday, May 13

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Miss Helen Masters: "The Post-War Home", 11: "Domestic Offices, Equipment and Maintenance".

Pharmaceutical Society of Great Britain (in the Small Hall of Friends House, Euston Road, London, N.W.1), at 2.30 p.m.—Dr. Philip Hamill: "Prescribing in War-time."

Institute of Metals (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Mr. William Thomson Halcrow: "Water Power and its Application to the Production of Metals" (Thirty-second Annual May Lecture).

Friday, May 15

Royal Institution of Great Britain (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. H. C. Plummer, F.R.S.: "Galileo and the Springtime of Science".*

Sunday, May 17

Association of Scientific Workers (Southern Area) (in the Refectory, University College, Southampton, at 2.30 p.m. Conference on "Science for Victory" *

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Deputy Borough Electrical Engineer in the Electricity Undertaking of the Woolwich Metropolitan Borough Council—The Town Clerk, Town Hall, Woolwich, London, S.E.18 (May 15).

Principal of the Walker Technical College, Oakengates—The Secretary for Education, County Buildings, Shrewsbury (May 16).

Civil Engineering Assistant—The Clerk to the River Ouse (Yorks) Catchment Board, 7 Langcliffe Avenue, Harrogate (May 20).

Inspector of Agriculture to serve during his early years as Lecturer in the School of Agriculture near Khartoum—The Controller, Sudan Government London Office, Wellington House, Buckingham Gate, London, S.W.1 (endorsed "Inspector of Agriculture") (May 25).

University Chair of Radiology (Therapeutic) tenable at Middlesex Hospital Medical School—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (May 26).

Head of the Chemistry Department—The Secretary, Robert Gordon's Technical College, Aberdeen (May 30).

Lecturer in Biology (part-time)—The Principal, Bishop Otter College, Chichester.

Lecturer (woman) in Biology and Horticulture—The Principal, The Training College, Lincoln.

Lecturer in Geography (part-time) at the Brighton Municipal Training College—The Education Officer, 54 Old Steine, Brighton.

Assistant (male) to the Public Analyst—The Secretary, Health Department, Grey Friars, Leicester.

SCIENTIFIC UTILIZATION OF MAN-POWER

THE White Paper on machinery for the joint planning of the War which the Prime Minister has now wisely issued does not add greatly to our knowledge, although it puts into precise terms much information which has hitherto been given either informally or piecemeal. It fills a gap, and the discussion on the adequacy of our machinery can now proceed on a sounder basis. That discussion and criticism have been carried over from Parliament into the Press, notably in the *Economist* and in *The Times*. In the latter Sir Edward Grigg's able article, which has drawn comment from Lord Hankey, Lord Chatfield, Lord Swinton, Lord Strabolgi, Prof. A. V. Hill and others, advocates the introduction of a single chief of a Combined General Staff standing outside and above the three Chiefs of Staff and presenting one opinion to the Premier and the War Cabinet. The question of the best system is a practical one and not all the critics agree. Moreover, counsel is sometimes confused, and the *Economist* and Prof. A. V. Hill seem to have kept closest to the heart of the matter. The *Economist* insists that the General Staff that is required must be one trained in the technique of co-operation of all three Services but belonging to none, so that the difficulties sometimes advanced as to whether the navy is to direct military or air force operations or *vice versa* do not arise. The recent appointment of Vice-Admiral Lord Louis Mountbatten as chief of Combined Operations is an indication, however, that we are moving further than the White Paper indicates in the direction of the integration on which Prof. Hill lays his stress.

What is required, Prof. Hill holds, is an integrated war staff, a high command, designed for the purpose of planning the war as a whole, not further additions to existing machinery. Already, as the White Paper points out, to ensure that operational planning and production planning are even more closely combined, there has recently been created the Joint War Production Staff. Prof. Hill argues that a complete war staff must include several elements not present in a mere combination of Service staffs. First, a chief of technical staff, guiding research, design and development with a view to operational needs and keeping the war staff informed on technical matters; secondly, a director of operational research responsible for the scientific analysis of the results of past operations and the critical study of current operational plans and methods; third, a joint technical liaison and intelligence officer for civil defence, who could help to devise offensive and defensive policy in relation to the actual effects of bombing. The neglect of these technical elements has, in Prof. Hill's view, had much to do with our failures and disasters.

Mr. Lyttelton's announcement of the formation of a production panel promises to remedy what has long been lacking—the use of technical men of authority to report on the weak places in production, give advice on the spot, or present findings to the highest authority. Field-Marshal Lord Milne's criticism of the joint war production staff is based on the staffing of its technical personnel from the Supply Departments instead of from the Service Ministries. He points out that chief technical officers of Supply Departments are not in the position to co-ordinate operational planning, because they are solely concerned with giving effect to a policy already laid down by the Service Ministry.

That criticism is valid up to a point, but unfortunately it is equally true that Service personnel have only too often proved incompetent to assess the significance for operational planning of technical developments. The basic charge against our operational planning is, in fact, that it has been too limited by Service traditions and experience, and too remote from the new possibilities of operations that technical advance has put at its disposal. The integration of the three Services in regard to a grand war strategy is not more important than the integration with them of the technical side to which Prof. Hill has directed attention.

The nearer we approach to our maximum effort, the severer are the limitations on our resources of materials or man-power, the more important are these questions of organization, co-ordination and integration at the centre. Improvisation can no longer be tolerated. Policy must be concerted and based on a view of the problem and situation as a whole, not of bits and pieces. Mr. Lyttelton has given clear evidence in his statement that he sees his problem as a whole, and the new White Paper provides at least some evidence that the Government is moving to the evolution of a common war strategy based on a corresponding vision and served by the appropriate instruments for its execution—though the pace may seem uncomfortably slow to some of the critics.

It is clear that the volume of criticism both within and without Parliament is having an effect in clearing away departmentalism and forging closer links and fuller integration between the three Services as a single fighting unit animated by the same spirit and the same conception of a common task. That integration, however, needs to be carried further and to embrace the production side of our war effort also. The beginnings of this were indicated in Mr. Lyttelton's first statement as minister, and its importance is further stressed in the latest of the long and valuable papers on war administration which have come from the Select Committee on National Expenditure. One of these, the seventh of the present session, while dealing mainly with matter falling within the sphere of the Ministry of Labour, raises the fundamental question of the distribution of man-power between industry and the Fighting Services.

This is the basic question of man-power policy. Without an answer to it we cannot judge how near Great Britain is to ensuring that every person in the community is contributing the best of which he or she is capable, nor can we make plans to that end. None of the several committees on man-power has as yet been charged with the task of finding out whether the proposed size and equipment of the armed forces represents the maximum military effort which the country can make. Each was subject to the precedent condition that the numbers to be taken for the Forces had already been determined by higher authority. The really fundamental question, namely, the distribution between the Forces and industry which will enable the national man-power, having regard to the ever-changing needs of the war, to make the maximum contribution to the combined striking force of the United Nations, has never been put to them.

The Select Committee considers that it is essential that there should be an independent permanent body to provide at least the materials for an answer to this question—to consider and calculate the effects of any particular allocation of man-power between industry and the Services. Its principal task should be to estimate the best allocation of man-power between industry and the Fighting Services, and as part of that task it should also have the duty of examining the allocation of man-power between the broad categories of industry. The principal recommendation of the seventh report is the establishment of a permanent committee for this purpose, independent of departments and reporting direct to the War Cabinet.

A body of this character would go far to supply the breadth of conception and to stimulate the firmness of execution which are necessary for the development of the maximum military strength. Had it been in existence, for example, opposition to the fuel rationing scheme based on the pressure for release of miners for the forces could scarcely have been engendered. Moreover, there would be less danger that the need for expansion of output, here or in the munition industries, might be met by further recruitment of labour when more careful employment of the workers already engaged would have achieved the same end. The mere meeting of employers' demands for labour is not proof that the country's capacity is fully utilized, for those demands are not necessarily a measure of the real needs of the country.

What emerges from the rest of this long and searching report is the crucial importance of the human factor, as is also stressed in the report on the human side of war production, recently issued by Mass Observation (Charge No. 3. An Inquiry into British War Production. Part 1. People in Production). This report deals with the efficient use of the available men and women, and it fully corroborates the detailed analysis and recommendations of the Select Committee. Efficient production and the exertion of maximum effort are the outcome not only of wise direction and concerted policy at the centre but also of assiduous and unremitting attention to detail everywhere, above all in those matters which affect the welfare and morale of the industrial population. In this connexion the Select Committee holds that the general responsibility for welfare should rest with the Ministry of Labour, which is relatively independent of the factories and is already the principal department concerned with the well-being of employees. The reconstituted regional boards should undertake the responsibility for supervising the efficient utilization of labour, labour supply in this way being treated as an integral part of the problem of production.

The forty recommendations of this report of the Select Committee are, in fact, largely directed against departmentalism and neglect to implement provisions already made. Emphasis is laid, for example, on stricter attention to securing that officials responsible for dealing with absenteeism, etc., exercise their powers fully under the Essential Work Order, as well as on the importance of disseminating technical knowledge, such as new methods of 'de-skilling' which bring about the more economical use of labour. Greater efforts to persuade managements to make arrangements for the part-time employment of women are recommended, and there is a pointed warning that it may be necessary to reconsider the exemption from compulsion of mobile women merely on the grounds that their husbands are with the Forces. How much this is a matter of organization and initiative is well brought out in a broadsheet of P E P (Political and Economic Planning) devoted to part-time employment.

Apart from welfare matters, there are pertinent comments on concentration. The policy of concentration, the report points out, will only have achieved its purpose if the total output from the industries concerned has been reduced to the minimum required to meet the needs of the Services, the civil population, and the export trade, with the minimum of labour and other resources, and if the labour and other resources released are actually transferred to essential work. Notably in the cotton trade these conditions do not appear to have been satisfied, and the Committee recommends emphatically that in determining the degree to which an industry should be concentrated the criterion should be the level of output required to meet war needs: The criterion for determining which establishments should be retained should be efficiency, and nucleus certificates should only be granted to the most efficient firms. Statistic of output and employment should be carefully examined and any unsatisfactory increase in the output per worker investigated. Closer check should be kept on the movements of workers released as a result of concentration schemes and, in particular, great care taken to make full use of persons in supervisory grades who are released as a result of concentration is recommended.

The importance of the distributive trades as a possible source of labour is once again emphasized by the Committee, and the observations on training include the recommendation that periodic investigations should be made to discover whether trainees are being properly placed and for the maintenance of contact between training centres and their more promising trainees to secure that, if they prove suitable, the opportunity for up-grading is not wasted. The cumulative effect of these detailed recommendations should be considerable, and if implemented they should go far to eliminate many sources of wasted man-power which, even if small in themselves, in the aggregate are increasingly serious in their effect upon production.

The eighth report of the Select Committee is concerned more specifically with the organization of production, and with the relation of production to strategy. It is indeed a lucid annotation of Mr. Lyttelton's statement on his functions as Minister of Production which was made between the drafting and the publication of the report. As in the report on labour, the Committee comments on the present improvisation and the absence of sufficiently prescient and progressive planning. The main need appears to be a better use of the available forces rather than an increase in their number. While recognizing the marked improvement of the last twelve months, the Committee is convinced that the Government, industrial management and the manual workers can and must do better.

It is for the Government to give the call and the opportunity to the other two main agencies to do their best, and for this reason the report gives most of its attention to Government direction and organization. On particular points which throw light on defects in organization, it notes the insufficient attention paid to the importance of greater specialization and to distributing contracts so that each manufacturer can concentrate on a limited number of types of product suitable to him, thus providing a sufficient run on each type to secure the most economical mass-production methods. Not enough attention has been paid to directing contracts, labour and materials to the most efficient factories where the man-hours on any job are lowest, or to the proper adjustment of work and capacity in the vast field of sub-contracts. Non-essential industries are still not properly regulated, and once again the importance of good personnel management and of proper arrangements for housing, transport and general welfare is reiterated.

On the general question of organization, the Committee reaches two main conclusions. First, there must be a supra-departmental authority to plan the programme, and secondly, the planning must be informed, based on an accurate appreciation of existing factors, and adequate forethought as to probable future developments. The evidence suggests that the programme for manufacture as transmitted to industry shows signs of inadequate foresight and sureness of decision. Accordingly it should have been possible for the Services to do better than they have in getting the right kind of weapons at the right time.

On the first point the Committee is satisfied that the new Minister of Production will be in a position to ensure unified direction. On the second, it stresses the vital importance of the Minister having at his disposal an adequately staffed intelligence and programmes organization, equipped with the means for collecting and interpreting all relevant data affecting the requirements of the Fighting Services, raw materials, supplies, manufacturing capacity and man-power. On this recommendation follows the further one that the Government should examine as a matter of extreme urgency what steps can be taken to improve the existing arrangements for ensuring that Fighting Services requirements are formulated with precision and so far as possible in advance, and that these are worked out without delay in terms of 'production jobs' and introduced into the production programme with adequate notice to the manufacturers concerned.

Passing from the vital task of relating, or rather integrating, the planning of production with the planning of operations and strategy, the Committee insists upon the necessity for a clear appreciation of the proper functions of the various agencies concerned with the execution of the national programme. Strong arguments are advanced for further decentralization, particularly in arranging and supervising the details of production. Great reliance should be placed on the regional organization of the supply departments, and revision of the present constitution and powers of the regional boards is recommended. Simultaneously, the Committee directs attention to the importance of keeping regional officers fully informed by their departments on all matters which may have a bearing on their duties, as well as to the necessity of a clear chain of responsibility if there is to be effective co-ordination of departmental activities at regional level.

In all this the report is recalling established principles of scientific management which have been neglected, with the usual results. The Committee also advocates measures for devolving responsibility on industrial organizations and for fitting the smaller factories accurately into the national plan. Stress is once more laid on the importance of supervision of execution, and it is recommended that departments should take more active steps to ensure both that good methods developed in one factory are made known to others and that the most efficient works are brought up to the fullest possible employment in priority over those that are less efficient. Similarly, in keeping with Mr. Lyttelton's own statement, the report recommends that all possible steps should be taken to enable workers in factories to have a true understanding of the war position and of the conditions affecting the work in which they are engaged, as well as to encourage the formation of joint production consultative and advisory committees.

These two reports are heartening documents. Among the best of the long series that the Select Committee has given us, they put a searchlight on many weaknesses in the planning, organization and execution of our war effort, accompanied by recognition of the immense effort that has already been made. It is clear that a number of their recommendations have been anticipated, and it may well be possible that further adjustments as yet not made known have brought planning and administration at the centre even more into line with the scientific principles so clearly enunciated in these reports. The emphasis which is simultaneously placed on the need for decentralization, for concentrating in the regional organization sufficient authority to act with speed and authority comes, however, nearer to us all. It should bring into the production field the basic requirement of a subordinate officer in all the Fighting Services, namely, a thorough understanding of his superior's stragetical plan as it affects his duties, and a reliance on his own initiative in its tactical application. Given subordinates in production who can meet these requirements, we should go far to ensure that maximum co-operation and response from the human element upon which in the end both efficient production and final victory depend.' Scientific workers cannot but welcome the evidence that further weight is being given to the technical factor in production and strategy, that the production genera staff is itself becoming competent to contribute t the formation of strategy, and that a scientific min and a scientific outlook are increasingly making themselves felt through the whole field of defence an offence, with the firm elimination of inefficiency o slackness wherever met, and steady, persisten improvement of methods as well as output an weapons. The new Appointments Department jus established by the Minister of Labour to take ove the Central Register and the Supplementary Registe implementing the reform promised last December is only the latest evidence of this new determinatio to make full use of technical and professional qualifications and to distribute ability on a more scientifi basis.

THE ANALYTICAL FOUNDATIONS OF CELESTIAL MECHANICS

The Analytical Foundations of Celestial Mechanics
By Aurel Wintner. (Princeton Mathematical Series No. 5.) Pp. xii+448. (Princeton, N.J.: Princeto University Press; London: Oxford Universit Press, 1941.) 36*s*. net.

FROM the beginning of civilization one need mus make itself felt, namely, for some form o calendar. In turn, this gives rise to the primitiv study of astronomy, involving some knowledge o the sun and the moon. When the planets are adde in the next stage, the astronomer needs an ephemeri or almanac; the modern Nautical Almanac, with it perfection within narrow limits, is the final outcome There have been many stages on the road, and som apparent interruptions. But the urge has alway been the same, essentially a practical one.

For the construction of the necessary tables c almanac some form of theory is required. Such theory need not be true in order to have value, an in fact it may be grossly in error. Thus the firs theory of any practical importance was the Ptolemai which assumed the earth to be fixed. On this wer based the Alfonsine tables, completed in the middl of the thirteenth century. The results may seem crud but with minor adjustments it is well to remembe that, surviving the transition from manuscript t printing, these tables served all practical need however imperfectly, for three centuries; it remain to be seen whether any modern tables will las nearly as long. Then came the Copernican theor with a different frame of reference, but the result when expressed in the form of tables were no bette if indeed they were not worse. Next came th Rudolphine tables, based on Keplerian theory. Her a great advance ought to have been clearly visibl but it escaped the appreciation of all but one remarkable man, Jeremiah Horrocks. However, this theor came at last into the hands of Newton, and from this point the problem assumed its modern form.

In this shape the Nautical Almanac, or similar ephemeris, represents the practical solution of a set of differential equations. These involve a number of numerical constants, the masses of the sun, planets and satellites, and their positions and motions at some given epoch, or equivalent information; the gathering of an adequate knowledge of such data has been a slow process of approximation. After Newton the early steps were taken by Clairaut and Euler. Afterwards we are chiefly indebted to Laplace, Le Verrier and Newcomb for planetary theory, to Hansen, Delaunay and E. W. Brown for lunar theory. These in their generation have all done their work well, so that to-day the approach to perfection in the solution of the two main types of gravitational problem may be considered quite satisfactory. For the time being, the working astronomer has been provided with the highway which he needs.

The construction of this highway means, as stated, the practical solution of a set of differential equations. In the process the astronomers, some of whom have been named, have taken what help the mathematicians of their day provided, but for the most part have evolved their own methods and, trusting to their own intuition, have had to take risks which the more rigorous mathematician might afterwards justify or might not. Thus in the course of providing for the main astronomical traffic, they have left a whole field of research open to the mathematician and one which if not inexhaustible does not show signs of being exhausted very rapidly. One question concerns the very nature of a system of differential equations, about which there is (p. 144) "Poincaré's dictum, according to which a system is neither integrable, nor non-integrable, but more or less integrable". Similarly, there is the problem of stability, which can be defined in several independent ways and must defy final solution until such definitions can be shown to be exhaustive.

There are, therefore, two different kinds of book which can be written about celestial mechanics. The one will treat mainly of the methods, usually approximate but practicable, which the theoretical astronomer uses with highly successful though limited effect. The other deals with the corresponding mathematical theory, the existence theorems needed for rigour, the provision of new and more powerful methods, and the discussion and development of points arising in the course of the severely practical problem of prediction. To the latter class the present work belongs, and it makes its appeal to the ambitious student who is not to be deterred by the technique of modern mathematics. Happily, the author is familiar with both sides of the subject, and has produced a book which, so far from being arid, is exceedingly interesting even to those who are not prepared to assimilate all its abstruse details. This is helped by unusually ample references to the historical development, ending in a final section devoted to this aspect. The value of this attention to the historical past would have been enhanced by the addition of a name index.

The course of development may be illustrated by reference to the lunar problem. Brown's treatment of this thorny subject, which gave even Newton a headache, was initiated by G. W. Hill. This is based on a periodic solution of an idealized form of the problem of three bodies, and no longer starts from a solution of the problem of two bodies. Hence arose the restricted problem, in which two bodies describe relatively circular orbits while the third is massless. The periodic motion of such a body, attracted but not disturbing, has been considered by Thiele, G. H. Darwin and with the greatest numerical detail by E. Strömgren. As a theoretical problem it has been considered by Poincaré and others. Thus, starting with transformation theory and dynamical systems, the book gravitates towards the restricted problem for which the ground has been prepared in earlier chapters. To the advanced student of celestial mechanics a knowledge of the analytical foundations is clearly indispensable, and Dr. Wintner's book can be recommended to his attention and careful study.

H. C. PLUMMER.

TENSOR CALCULUS

An Introduction to Differential Geometry with Use of the Tensor Calculus

By Prof. Luther Pfahler Eisenhart. (Princeton Mathematical Series, 3.) Pp. x+304. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1940.) 21*s.* 6*d.* net.

THIS book gives a thorough introductory study of the properties of ordinary points in the differential geometry of curves and surfaces in 3-space. Chapter 1 gives an account of twisted curves, Chapter 2 describes the tensor calculus. In Chapter 3 this calculus is applied to investigate the intrinsic geometry of a surface, that is to say, those properties which depend on the first fundamental form. Chapter 4 develops those properties which derive also from the second fundamental form and therefore characterize the surface as viewed from the enveloping space.

On account of the expository character of this text-book, it is Chapter 2 which gives rise to some reflections. In introducing the notion of a tensor it has become the custom, which is also adopted in this book, to emphasize heavily the transformation aspect and to leave the student very vague as to the essential simplicity of the tensor idea. There is, however, an easier and perhaps more logical approach by means of the indefinite multiplication of ordinary vectors. If $\mathbf{a}$, $\mathbf{b}$, $\mathbf{c}$ are vectors (tensors of the first order) and a semi-colon denotes indefinite multiplication, ordered combinations such as $\mathbf{a}\,;\,\mathbf{b}$ or $\mathbf{a}\,;\,\mathbf{b}\,;\,\mathbf{c}$ or the sums of like combinations are tensors of the second and third orders respectively. Contraction then consists of replacing indefinite multiplication by scalar multiplication. Thus the tensor $\mathbf{a}\,;\,\mathbf{b}\,;\,\mathbf{c}$ can be contracted for example to $(\mathbf{ab})\mathbf{c}$ by taking the scalar product of the first pair of vectors. In applying the tensor calculus to differential geometry, it often becomes necessary at some stage to use a co-ordinate system, say, x^r. We can then introduce at any point P a local system of vectors, or a basis, $\mathbf{e}_r$, such that the vector PQ, where Q is an adjacent point x^r+dx^r, is $d\mathbf{s} = \mathbf{e}_r dx^r$, and at the same time we define the reciprocal basis $\mathbf{e}^r$ by the relation $\mathbf{e}_r\mathbf{e}^s = \delta_r$ in terms of Kronecker's deltas. The fundamental quadratic form is then simply $d\mathbf{s}d\mathbf{s} = \mathbf{e}_r\mathbf{e}_s\, dx^r dx^s$, which shows that the number usually called g_{rs} is a scalar product of two vectors of the basis. Any vector at P can be expressed either in terms of the basis or in terms of the reciprocal basis. Thus if $\mathbf{a} = a_r\mathbf{e}_r = a_s\mathbf{e}^s$ and

$\boldsymbol{b} = b^r\boldsymbol{e}_r = b_s\boldsymbol{e}^s$, the tensor $T = (\boldsymbol{a}\,;\,\boldsymbol{b})$ can be expressed in the three forms

$$T = a^r b^s(\boldsymbol{e}_r\,;\,\boldsymbol{e}_s) = a^r b_s(\boldsymbol{e}_r\,;\,\boldsymbol{e}^s) = a_r b_s(\boldsymbol{e}^r\,;\,\boldsymbol{e}^s),$$

which show the so-called contravariant, mixed and covariant indices, and the relative unimportance of these adjectives.

To define the Christoffel symbol of the second kind (the first kind has no essential applications) we write as definition

$$\frac{\partial \boldsymbol{e}_r}{\partial x^s} = \frac{\partial^2 \boldsymbol{s}}{\partial x^s \partial x^r} = \begin{Bmatrix} t \\ rs \end{Bmatrix} \boldsymbol{e}_t, \text{ whence } \frac{\partial \boldsymbol{e}^r}{\partial x^s} = -\begin{Bmatrix} r \\ ts \end{Bmatrix} \boldsymbol{e}^t.$$

These results together with the vector differentiation operator $\nabla = \boldsymbol{e}^i\partial/\partial x^i$ contain the whole manipulation of differentiation. For example, we have the tensor

$$\nabla\,;\,\boldsymbol{a} = \boldsymbol{e}^i\frac{\partial}{\partial x^i}\,;\,a_r\boldsymbol{e}^r = (\boldsymbol{e}^i\,;\,\boldsymbol{e}^r)\left[\frac{\partial a_r}{\partial x^i} - a_s\begin{Bmatrix} s \\ ir \end{Bmatrix}\right],$$

which gives the covariant derivative and shows that it is a tensor.

The considerations thus briefly indicated are of general application to n-space and to tensors of any order. Moreover, they render obvious the proof of, and the connexion between, such theorems as 16·6 and 17·6, which in spite of their dissimilar enunciations are merely statements regarding the basis and its reciprocal. Similarly, the Frenet formulæ in general co-ordinates follow at once from their ordinary vector form.

The book is beautifully printed and has many excellent diagrams and illustrations. It has also another claim to the student's attention, namely, the large number of exercises, many of which contain important theorems. There are a bibliography of works to which the author refers and a useful index.

L. M. Milne-Thomson.

FORENSIC SCIENCE

Science for the Prosecution

By Dr. Julius Grant. Pp. vii+302+25 pl. (London: Chapman and Hall, Ltd., 1941.) 15*s*. net.

Forensic science, or the application of scientific investigation to the purposes of the law and the administration of justice, is an outcome of the older subject of forensic medicine or medical jurisprudence. Whereas forensic medicine deals primarily with offences against the person, forensic science covers a somewhat wider field and includes the investigation of offences against property.

It is only within comparatively recent years that the latter subject has assumed an important position in the investigation of criminal offences. The importance of forensic medicine, on the other hand, was recognized in Great Britain so long ago as the end of the eighteenth century, when voluntary lectures were given on it at Edinburgh, and were followed by the establishment by the Crown of a chair of forensic medicine in 1807 at the University of Edinburgh. This was the first of its kind in any English-speaking community. Although this subject has now become an integral part of the medical curriculum, and each medical school now has its lectureship on the subject, there is only one other full-time chair complete with its department in Great Britain, namely, that of the University of Glasgow.

Forensic science has gradually evolved from the older subject, and in connexion with this may be mentioned the names of Lombroso of Turin, Locard of Lyons and Söderman of Stockholm. Institutions for the study of forensic science are (or were) in active operation in Paris, Lyons and Lille, that o Paris being founded in 1912. In Great Britain, the Metropolitan Police Laboratory was established in 1935, and this was followed by the establishment by the Home Office of Regional Forensic Science Laboratories at Nottingham, Cardiff, Birmingham, Preston and Wakefield. Although these laboratories are there to assist the police, the reports issued from them are naturally entirely independent as to whether they favour the prosecution or the defence, and they may be used therefore afterwards in a court of justice by either side.

Dr. Julius Grant has written a most interesting and valuable book on the methods used in forensic science. As he says in his preface, he has adopted a semi-popular treatment of the subject, the book being primarily intended for the lay reader and to introduce the subject to the lawyer. One feels that although it has this general appeal, it would be better for the reader to have some knowledge and interest in science before he could fully understand and appreciate its contents. It covers a wide field embracing the work of the physicist, the chemist the biologist, the pathologist and the psychiatrist In other words, there are various chapters on optica methods, including ultra-violet and infra-red rays X-rays, spectroscopy, the microscope and the camera, chemical methods, blood-group tests and serum analysis, and lastly psychology and crime. Of all the methods discussed, probably the most important and the one most frequently used is that of microscopy. This is fully admitted by the author especially when the microscope is used in conjunction with the camera; but even the camera may not always be necessary.

Methods of examination by ultra-violet and infra-red rays are extensively used in this type of work and the chapters dealing with these give a very clear outline of their importance and use. Although X-rays have not been used to any great extent up to the present, the most striking results have been obtained from the examination of oil paintings of the 'Old Masters'. The pioneer work of Prof. A. P Laurie must always be remembered with regard to this type of investigation.

The chapter on chemical methods covers a wide field, from the detection of poisons to the decipherment of charred documents, the latter having assumed a certain degree of importance during the past two years. The blood-alcohol test is also dealt with, and one is glad to see the very fair opinion given of the value of the test.

The general reader will also obtain a good knowledge of the blood-grouping tests with regard to blood stains and paternity cases, and finally there is an interesting discussion on psychology and crime It is doubtful whether such methods as those described in the use of the 'lie detector' would ever be tolerated in Great Britain.

In conclusion, it must be said that this book contains an amount of interesting information, interestingly set forth within a comparatively limited space, and can be recommended not only to those for whom it was apparently written, but also to those who are actively engaged in forensic laboratory work. The book is well illustrated with plates and diagrams.

J. Davidson.

COLOURS IN FOOD

THE practice, now widespread, of adding colouring matter to foods has not always found favour with the authorities, as is instanced by the heavy penalty of £500, imposed by an Act of 1816, for selling colouring agents for the darkening of beer. This was mentioned by Mr. D. J. T. Bagnall, city analyst for Hull, in his paper opening a discussion on "Colours in Food" held on April 13*. Foods are coloured by the addition of (1) metallic salts such as copper sulphate, although the use of copper salts is now prohibited in Great Britain; (2) natural colouring matters such as cochineal, saffron or annatto; (3) synthetic dyes, the principal method now in use. Attractive colours may also be imparted to certain foods by such processes as smoking or pickling.

The principal reasons for colouring food are to replace colour lost in processing or to imitate an article of superior quality. The process of canning entails partial loss of the natural colouring of the food, and this deficiency in tinned goods is frequently made good by the addition of artificial dyes. The need for this artificial colouring is lessened if the fruit or vegetables are freshly gathered and carefully processed, when the loss of colour is reduced to a minimum. The other motive for colouring foods, namely, to imply superior quality, is wholly reprehensible, according to Mr. Bagnall, who suggested that to colour cakes yellow to imply the presence of eggs is as serious an offence as to state on the label "Made with eggs" when in fact no eggs are present. Yellow colouring matters are added to butter and to cakes to suggest richness of quality. Chocolate cakes and chocolate biscuits are often dyed a deep brown colour to suggest the presence of cocoa, of which the actual amount may be so small that the addition of artificial essence is necessary to impart a chocolate flavour. Food dyes are sold under such poetic descriptions as 'egg yellow', 'gooseberry green', 'pea green', 'kipper brown', 'spinach green', and 'brawn pink'. Their mission is obvious from their names! A "perfect substitute for eggs" recently examined in Hull consisted of water (96·3 per cent), oil (0·5 per cent), sodium bicarbonate (1·0 per cent), cellulose gum (2·2 per cent) and a yellow dye. Without the dye this sticky liquid would have deceived no one. In the opinion of Mr. Bagnall the addition of colouring matter to foods of lower quality in order to render them more attractive is permissible only if the purchaser is notified of the lower quality and if the presence of the added colouring matter is declared.

Great Britain is the only leading country which has not a legal schedule of permitted colours. Any colouring matter may be added to food, provided it is not injurious to health, except compounds of antimony, arsenic, cadmium, copper, mercury, lead and zinc. Gamboge, picric acid, victoria yellow, Manchester yellow, aurantia and aurine are also prohibited. Other countries, including the United States, France, Canada, Australia, New Zealand, Italy, Spain, Sweden and Denmark have lists of permissible colours. Which of these two systems is to be preferred? Injuriousness to health is difficult to prove, and the effect of a dye on test animals may not be the same as on the human organism. The proportion of added colour in the food is so small that the dye could scarcely be harmful unless highly toxic, but this argument ignores the possible cumulative effects of frequent small doses. Mr. Bagnall is inclined to the view that only specified dyes proved to be non-injurious to health should be permitted, and that official standards of purity should be set up and enforced.

In the discussion which followed this paper it was suggested that Mr. Bagnall had over-emphasized the tendency to use food colours for purposes of deception. Delicate tinting of an article of food often made it more acceptable to the public, who demanded such colouring. Artificial colouring serves to compensate for the unavoidable deterioration of colour which often occurs with time and also to standardize the products.

Prof. J. W. Cook dealt with biological properties of dyes, with particular reference to those used for colouring foods. Synthetic colouring matters have long been known to have various kinds of biological activity. The staining of organisms by trypan blue and trypan red played an important part in the early development of chemotherapy, and the antiseptic action of such dyes as gentian violet, methylene blue, brilliant green and acriflavine has been much utilized. The earliest sulphonamide drugs were azo dyes (prontosil is a sulphamido derivative of chrysoidine, which has been used as a food dye). Dyes also find application in diagnostic tests. With these medicinal dyes it is scarcely surprising that their pharmacology has been much investigated. In the case of dyes used for colouring food the situation seems less satisfactory in this respect.

In a report published by the Ministry of Health in 1924 it was stated that more than ninety different dyes were supplied for colouring food in Great Britain. The actual number in common use appears to be about twenty-five, and of these the following seven are used in the largest amounts: Tartrazine, Ponceau *RS* or *2R*, Orange I or *IS*, Orange II or *GS*, Amaranth *AS*, Erythrosine *AS*, Rhodamine *B* or Rose *BS*. The first six of these are included in the list of food colours permitted in the United States. Four of them are included in a list of thirty-six synthetic dyes which are stated in Martindale's "Extra Pharmacopœia" to be harmless for colouring foods. Recent original literature contains comparatively little reference to the biological properties of food-colouring matters. Facts are accumulating, however, which suggest that the time has come when current practice and the existing regulations relating to this matter should be reviewed.

The causes of dermatitis associated with substances used for dyeing fur and hair have been much studied by H. E. Cox[1], who concluded that in a large proportion of cases the agent primarily responsible is *p*-phenylene diamine. This undergoes atmospheric oxidation to quinone di-imine, which is a powerful irritant. In this connexion it may be remarked that *o*-aminoazotoluene, which is stated to have been used as a food dye, is metabolized by rabbits to the diacetyl derivative of *p*-toluylenediamine[2].

Baer[3], in 1934, recorded a case of dermatitis which was attributed to a green synthetic colouring matter present in salads. The symptoms included an erythematous eruption on the neck, shoulders and arm. This suggests a photodynamic action, but it is stated that the eruption occurred on covered areas of skin as well as on uncovered areas. It is now recognized that many fluorescent dyes, introduced into the body, may lead to lesions of the skin on exposure to light, due to photo-sensitized oxidation of protein or amino acid[4]. This possibility should be borne in mind in connexion with the use of fluorescent dyes to colour food.

---

* Summary of contributions to a discussion held in Leeds on April 13 at a joint meeting of the Yorkshire Section and the Food Group of the Society of Chemical Industry.

Two cases of dermatitis due to handling artificially coloured citrus fruits were reported in 1937[5]. The principal dye used for this is Yellow *OB* (*o*-toluene-azo-β-naphthylamine). In these and similar cases constant and repeated exposure to the dye probably produced hypersensitivity. Toxicity experiments carried out by Climenko[6] with *o*-toluene-azo-β-naphthol, an oil-soluble dye used also for colouring the skin of citrus fruits, showed that its acute toxicity is very low. The maximum dose after which recovery took place was 20 gm. per kilogram of body weight. No serious adverse effects resulted from daily administration for six months of doses up to 100 mgm. per kilogram of body weight. Many medicinal dyes are far more toxic than this. In cases of acute toxicity the dye often appears in the urine, and the liver, kidneys and other organs are stained with the dye. These organs also show pathological changes. It is of interest that Huggett and Rowe[7] have shown that many azo dyes, particularly those which are prepared from tetrazotized diamines and aminonaphthol sulphonic acids, are effective inhibitors of blood clotting.

Malignant tumours of the liver may be produced in rats and mice by administration of large doses of two azo dyes which have been stated to be in use as food-colouring matters. This was shown by Yoshida[8] in the case of *o*-aminoazo-toluene and by Kinosita[9] in the case of *p*-dimethylaminoazobenzene ('butter yellow'). Their observations have been amply confirmed and although it is believed that these dyes are not now used for colouring food their use should be prohibited. Similar pathological changes in the liver are induced in mice by 2 : 2′-azonaphthalene[10]. These circumstances led to tests being carried out with food dyes having structural resemblance to these, with the co-operation of Dr. J. J. Fox, who supplied valuable information as to the dyes in most common use and procured samples of them. Six azo dyes were selected for test, namely, Ponceau *RS*, Orange *IS*, Naphthalene Orange *GS*, Naphthalene Fast Orange 2*GS*, Amaranth *AS* and Metanil Yellow *YKS*. Mice were fed on brown bread soaked in aqueous solutions of the dyes so that each mouse received 15–20 mgm. per week. This would correspond with about 60 gm. for a man. The experiments were of adequate duration, but no tumours were obtained[10].

Five of the six dyes used in these tests are water-soluble sulphonates and hence would be rapidly excreted. Further tests were therefore carried out with Yellow *AB* and Yellow *OB*[11]. These two oil-soluble azo colours do not appear to be used in Great Britain, but are in common use in the United States. The dyes were administered to mice by feeding, by application to the skin, and by subcutaneous injection, but no tumours have been obtained in the experimental animals[12].

Thus, there is no evidence that any of the food dyes except Butter Yellow and *o*-aminoazotoluene are associated with carcinogenic properties. The use of these as food colours is probably now obsolete. In any case, it may be noted that the amounts used to produce tumours in animals were proportionately very much in excess of those which would be used to tint foods. It would be very difficult to determine whether repeated administration of small amounts of these food dyes during many years would be followed by tumours or other pathological conditions in the human subject.

Commercial colours which are used for dyeing fabrics are liable to contain toxic impurities, and for food colouring purposes specially purified dyes are manufactured. Analytical control, particularly in regard to certain metals, is important, and Dr. D. A. Harper and Mr. N. Strafford described methods which can be used for the rapid spectrographic determination of minute amounts of arsenic, lead, copper and other heavy metals in food dyes and medicinal products.

The determination of minute amounts of metallic impurities in organic substances by colorimetric methods is a time-consuming and expensive operation and consequently spectrographic methods possess many attractions. Although methods for the determination of traces of some metallic impurities in organic substances have been described the determination of arsenic has hitherto not been provided for. The present method will detect 0·5 parts per million of arsenic (As_2O_3), lead and copper, also antimony and tin if required. 1 gm. of the sample is wet-oxidized and the metallic sulphides precipitated along with cadmium sulphide, which acts as carrier and also as spectroscopic internal standard. The mixed sulphides are filtered off on a powdered graphite filter bed and, after drying, the mixture of sulphides and graphite is arced in the D.C. arc between graphite electrodes in front of the slit of a Hilger medium spectrograph. The tests are carried out in duplicate, and by means of a Hartmann diaphragm the spectra are photographed on both sides of the spectrum of a 'specification test' in which the same amounts of the reagent have been used and to which have been added the amounts of the metallic impurities corresponding to the specification limits. If necessary, additional standard spectra corresponding to limits both below and above specification limits can be employed. By examination of suitable spectrum lines it is possible to indicate whether each metallic impurity in the sample under examination is equal to, above, or below the specification limit, and an estimate of the actual amount of each present can readily be made.

The method is similar in accuracy to the usual colorimetric methods, and it offers considerable economies. When applied on 'mass production' lines the overall cost per sample is approximately one fifth of that of the colorimetric method. Of more importance in present circumstances is the fact that only one quarter to one third of the man-power is required.

THE CAUSE OF EARTHQUAKES

By ERNEST TILLOTSON

THE term 'earthquake' means vibrations of the ground. These vibrations are caused by the passage of various types of waves through the ground, which has elastic properties. The ground vibrations are kinetic energy, which must be released consequent on the disappearance of some form of potential energy. The form this potential energy takes, how it is released, but more particularly how it arises is the problem before us.

The data are multitudinous, and excellent recent papers covering some of the field are "Seismology" by Beno Gutenberg[1] and "Tectonic Processes now in Action"[2] by the same author. First consider the immediate cause. The potential-kinetic change might occur by sudden collapse, expansion or fracture. The first, caused by mining subsidences and the collapse of underground cavities, is of minor importance. The second may occur by chemical change or by change of state, for example, in magma basins or by sudden contact of percolating water with heat reservoirs—possibly causing such outbreaks as the Montserrat (West Indies) swarms. Apart from such phenomena and the fact that earthquakes and active volcanoes are associated with geologically recent mountain chains, there is little connexion between earthquakes and volcanoes. The third cause, by fracture, appears to be more frequent. Most normal strong earthquakes originate near the base of the 'granitic' layer at a depth of some 16 or 17 km. below the earth's surface ('sedimentary' layer 0–10 km. thick, 'granitic' layer 13 km. thick, 'intermediate' layer 26 km. thick), and it would appear that the immediate cause of most of these shocks is the application of pressure to rocks until they fracture. The total energy released by earthquakes per annum is near 10^7 kilowatts, and most of this is released by one or two great shocks. The focus of one shock as determined from instrumental evidence may be the place where fracture starts, though this fracture may spread quickly in any direction. That such pressure exists is sometimes first seen in extensive ground tilt; for example, the recent great Chillan (Chile) earthquake[3], though such ground tilt cannot yet be used to foretell the time or place of a possible future shock. Plastic flow or a succession of small shocks may alternatively dissipate the energy. Small foreshocks may presage larger earthquakes, though again such forerunners cannot yet be recognized as such. We have no independent means at present of probing the local strength of the 'granitic' layer to discover where rupture is likely to take place. Often between the accumulation of stress and the earthquake some small additional force such as an extra high tide, or great change in barometric pressure, perhaps a shaking from some independent distant earthquake or a mining subsidence may act as a 'trigger', thus releasing the larger energy.

Periodicities in earthquakes are still *sub judice*. With the present careful collecting of data better judgment may be passed after another 400–500 years. Artificial earthquakes caused by explosions of such material as gelignite (even the Oppau explosion—Jeffreys and Wrinch) only give rise to very minor pulsations. One of the strongest earthquake shocks has about 10^{25} ergs (Chile 1922); rather less energy was expended by the Turkish earthquake[4], less still by the San Francisco earthquake of 1906 and the Indian earthquake of 1934. To be humanly perceived an earthquake must have 10^{11} ergs, and to be recorded by a seismograph 10^8 ergs.

The long-range, or fundamental, cause of earthquakes would appear to be more important. What forces lead up to the rupture of rocks causing an earthquake and in what manner do they arise ? The forces are sometimes forces of compression, on occasion of tension and often they are shearing forces. Numerous combinations of these doubtless occur, and these may possibly arise in the following ways: Geosynclines are of paramount importance in the formation of large-scale sedimentary deposits, and in the compression of these deposits to form mountain chains. In depth the geosyncline must include the 'sedimentary', 'granitic' and 'intermediate' layers which altogether may reach a thickness of some 40–45 km. Flow to give some measure of isostatic compensation must begin at some distance below this. Should it so happen that as the deposition of sediments is maintained, the compensation keeps pace with it, the sides of the geosyncline might become so steep that tension would develop by gravity action in the various layers. If this tension is sufficient to overcome the cohesion in the rocks, these break up into blocks and the act of breaking gives rise to earthquakes. The folding of the sedimentary deposits in the bottom of the geosyncline may also cause earthquake shocks if the elastic limit of these rocks is exceeded and they fault instead of bending quietly. Geosynclines could scarcely be less than, say, 700–800 km. in horizontal extent and are often much larger. Their functioning must depend on the presence of a substratum underneath the 'intermediate' layer perpetually ready to yield under the action of loads above it. The yielding need not be continuous in time, and indeed several peculiarities are explained if it is not. A sudden yielding after a period of gradually increasing tension, compression or twisting would be much more likely to produce the sudden ruptures giving rise to earthquakes than a gradual continuous yielding.

Beds of rocks of different geological periods are separated in many places by unconformities and in others by sudden alterations in lithology. Periods of quiet deposition of sediments are followed by upheavals and then new conditions of deposition. Gradual transition from one formation to another is an exception rather than a rule. Does this not point to sudden accommodation isostatically in the basin of deposition showing that the yield point of the underlying material had been attained ? Joly assumed that this was caused by blanketed heating by radioactive material, though this need not be the only possible cause. The material may have an elastic yield point which the weight of the superimposed material may attain without the addition of heat. The period between a certain area being a basin of deposition and its rising to mountain peaks may be of the order of 10–100 million years, though in certain circumstances this estimate might be reduced. The forces are acting over long periods of time, and this may explain why we find with our limited period of observation that earthquakes tend to occur in the same localities as they have always occurred within the experience of our historical records. It is possible for a small basin of deposition to go through a cycle much more rapidly if the material underneath is sufficiently yielding. Minor oscillations within the geosyncline are sometimes apparent and perhaps the 'granitic' and 'intermediate' layers may yield locally.

The strength of the 'sedimentary' layer may be of the order of 10^9 or 10^{10} dynes per centimetre and the viscosity of the immediate interior according to one estimate is of the order of 10^{22} poises.

During such a period of yielding the sedimentary rocks may become folded and faulted, the process being accompanied by earthquakes with foci in the 'sedimentary' layer, seldom in the 'granitic' layer, and less frequently in the 'intermediate' layer. The movement may be started by any load of sufficient magnitude applied in one place such as the accumulation of ice during an ice age. Scotland and Fennoscandia are now rising after their Pleistocene ice has been melted away, while south-east England is falling at the rate of about a foot per century. This twisting may have set up strains in the upper layers, causing the North Sea earthquakes. Many of the Norwegian earthquakes are superficial.

Experiments made in the Geophysical Laboratory at Washington tend to confirm that rocks behave differently under forces gradually applied from what they do under forces applied quickly. The material of the earth's crust is continually tending towards hydrodynamical equilibrium. To this equilibrium the crust is continuously approaching with the passage of time, but the equilibrium is never absolutely attained owing to the resistive strength of the materials. This is Dutton's conception of isostasy. The work of Hayford, Heiskanen, the Indian Ordnance and Geological Surveys and others tends to show that although Hayford's numerical conception of isostasy has distinct computational advantages in geodesy, involving as it does gravity anomalies, yet on the available evidence it is effective over about one per cent of the earth's surface and ineffective over another 0·75 per cent. This is the extent of the earth's surface so far surveyed in this manner. Tests are now being made with seismographs in the neighbourhood of the Grand Coulee and Shasta Dams in the United States to see whether or not a small area suddenly loaded gives the necessary conditions for small earthquakes to occur. Numerous small earthquakes occur near Boulder Dam, but the pre-dam seismic history is not known.

Earthquakes with epicentres in areas subject to recent geological tectonic activity tend to have their foci in the 'sedimentary' layer, whereas foci in the 'intermediate' layer and down to 300 km. depths show some correlation with zones of Tertiary mountain building. There is still something to be said for the contracting earth theory though perhaps such forces as the *Polfluchtkraft* require more careful comment. Much seems to depend on the structure of, say, the upper 100 km. of the earth. The bed of the Pacific Ocean appears to be the only region in the world where the 'intermediate' and 'granitic' layers are absent. In the Pacific region the sima comes right to the surface, while elsewhere in the world sial overlies the sima. The vertical discontinuity is near the andesite line, and in North America it is apparent when seismic surface waves of about 20-sec. period and 70-km. wave-length cross from the Pacific Ocean bed to the land. There is much loss of energy. The discontinuity must extend at least some 25 km. down, but its vertical extent does not exceed 200 km. Such loss of energy is not apparent when similar waves cross other ocean beds, and if the evidence of seismic sounding is confirmed the North Atlantic depression has probably been caused by flexure and not by faulting.

Around the circum-Pacific line of instability in Japan, the Philippines and California, the directio of faulting shows the land moving southerly wit respect to the seaward side. Is this the *Polfluchtkra* at work in the Pacific region ?

The Atlantic and other regions would appear t be more doubtful. We must be careful, however not to take *all* surface faults to be the *cause* of earthquakes. The cause of an earthquake and its focus may be more deep-seated, and the surface fault ma be a *result* of the shock, not the cause of it.

Thus far we have not yet dealt with deep-focus earthquakes, that is, those with foci between 300 and 700 km. deep. The work of Scrase (recognition of *pP*, etc.), Turner (waves at the antipodes), and Stoneley and Jeffreys (small amplitude *L* and *M* show that these undoubtedly occur. The Brunner depth chart constitutes a quick working tool for finding such depths. It appears that these deep focus earthquakes could be caused by displacement resulting from the action of convection currents. The experiments of H. Bénard in 1900 showed the presence of convective 'cells' in fluid between two parallel surfaces maintained at different temperatures. Pekeris has continued this work. Deep-seated heat from th still molten core of the earth some 3,500 km. in radius may give rise to discontinuous geologically slow convection currents from this depth to, say, the 700 km discontinuity. This discontinuity may be between vitreous and crystalline basic material and is probably marked by a magnetic discontinuity also. Below 700 km., forces would be dissipated by plastic flow but just above 700 km. the forces might accumulat until rupture, causing an earthquake, could occur.

The part played by radioactive heat at these depth is uncertain, though heterogeneities in the interior are more important than homogeneities in deciding where convexion currents shall be, and where th elastic potential shall accumulate. Western South America, the Sunda Sea near Java, and the region between Japan and New Zealand are very activ regions at the moment. A series of observations o the direction of faulting taken over large areas o the earth's surface, also the careful integration o seismograms to discover the initial movement at the focus of deep-focus earthquakes would perhaps assist in finding the direction of deep-seated convection currents should these in reality exist.

RAMAN'S THEORY OF SPECIFIC HEAT OF CRYSTALS

By DR. W. H. GEORGE
Chelsea Polytechnic, London

WHEN, in 1907, Einstein published his work on the specific heat of solids, nothing was known of X-ray crystallography. Crystals were apt to be regarded as a highly specialized form of solid matter Now, as a result of the wide application of X-ray analysis to all solids, the crystalline state is known to be the normal stable state of solids. Theoretically the crystal is a periodic three-dimensional grouping in space of an immense number of atoms, ions or molecules held together by interatomic or intermolecular forces. The unit cell, the smallest portion of the crystal to contain all the groupings of atoms characteristic of that particular form of the substance, is very much smaller than the smallest visible crystal. Nevertheless, the strength of diamond and the greasiness of graphite are inherent in the two different patternings of carbon atoms in the two different unit cells.

Properties of solids may be divided into the macroscopic, modified greatly by the shape and size of the individual specimen, and the sub-microscopic, inherent more in the patterning within the unit cell. This division of the physical properties of solids raises crucial questions when thermal properties are considered. On the kinetic theory of heat, heat is 'a mode of motion'. Are the thermal vibrations of atoms in a solid characteristic of the unit cell, or are they dependent more upon the size and shape of the particular crystal, differing for different crystals of the same substance? Sir C. V. Raman discusses these problems in a summary of his work published with six experimental studies on the subject in the *Proceedings of the Indian Academy of Sciences* (A, 14, November, 1941). The following is an account of the theory and of Raman's criticisms.

Raman's Specific Heat Theory

Let it be supposed that the thermal vibrations of a crystal may be described without reference to the fine structure of the solid. We shall be dealing with elastic vibrations. Their modes and frequencies will depend upon the speed of propagation of elastic waves and upon the dimensions and boundary conditions of the crystal. Oscillatory motions of large groups of atoms will be involved, and the larger the crystal the smaller would be the frequency differences between the successive possible modes of vibration. In the limit, the elastic vibrations of a visible crystal would give a continuous spectrum of frequencies. When, however, the wave-length of these vibrations becomes comparable with the size of the unit cell, the possibilities of another type of vibration must be considered. Here we should be concerned primarily with vibrations of atoms about their mean positions in the unit cell. The dimensions of the crystal would have a negligible influence and the frequencies of the vibrations would be much greater. Although the principal modes of vibration would be the same for all unit cells, larger-scale oscillations might occur in which there is a repetition in cells of a superlattice, the spacings being an integral multiple of the unit cell. All such vibrations would be monochromatic and would give approximately a continuous spectrum only if the number of types of superlattice was very great. In general, the first type of vibration would tend to give a continuous spectrum and the second a line spectrum in the infra-red region of the spectrum.

The distribution of thermal energy between the two types of vibration is treated as follows. The largest part of the thermal energy is taken to be that associated with the unit cell. If there are p atoms in the cell, there will be $(3p-3)$ modes of internal vibration and 3 translations for the cell as a whole. If p be fairly large, the $(3p-3)$ degrees of freedom appearing as vibrations would greatly exceed in number the 3 degrees of translation. Considering the superlattices and taking one in which the cells have twice the edge-length of the lattice cells first chosen, we have $(24p-3)$ modes of internal vibration of the atoms and 3 translations. The former $(3p-3)$ modes of vibration will be included, as well as others approaching them in character. In addition, new modes of vibration previously reckoned as simple translations of the unit cell would occur. Unless p is very small, not many superlattice vibrations need be considered. The number of vibrations of the elastic type bears to the total number of degrees of atomic freedom a ratio of the same order of magnitude as the ratio of the volume of an individual atom to the cube of the limiting wave-length. When, therefore, the wave-length limit is even moderately large in relation to the lattice spacings of the crystal, the energy of such vibrations is a negligible fraction of the whole.

The Debye Specific Heat Theory

The specific heat theory of Debye is criticized by Raman on the grounds that it associates the thermal energy of the crystal with that of elastic vibrations. Experimentally it is found that elastic vibrations travel with high speed, whereas heat energy travels very slowly indeed, at diffusion rates. The limits of using a discontinuous structure as an approximation to a continuous structure or vice versa are illustrated by the well-known example of the modes of vibration of a periodically loaded string and of a uniform string. While the specific heat curve can be uniquely derived from the vibration spectrum, a knowledge of the specific heat data is insufficient for a determination of the vibration spectrum. The Debye formula with an appropriately chosen limiting frequency fits the specific heat data in certain cases, but fails for several elements crystallizing in the cubic system. The Debye function is the integrated sum of a continuous sequence of Einstein functions over a range of frequencies with weights proportional to their squares and a sharp cut-off at an upper limit. Experimental data which fit a Debye function should therefore equally be capable of being represented as the sum of a finite number of Einstein functions with appropriate frequencies and weight factors.

In Einstein's earliest papers, he pointed out that approximate relations between atomic frequencies and elastic constants were to be expected from elementary considerations. No special significance can therefore be attached to the fact that elastic constants calculated from the specific heats come out of the right order of magnitude.

Born's Theory of the Cyclic Lattice

The Born theory is criticized on the grounds that in essence it is based on concepts derived from the macroscopic behaviour of elastic solids of the same kind as are used by Debye. Born's theory rests on his postulate of the 'cyclic lattice'. All the atomic displacements are taken to be periodic in a volume having the same shape as the unit cell of the lattice but of very great size in comparison with it. The postulate makes no distinction between the atomic vibrations of high frequency and the elastic vibrations of low frequency. All the possible vibrations are assumed to have wave-lengths which are submultiples of the external dimensions of the crystal. This is in contrast with the Raman theory, where the unit cell or integral multiples of it are taken as determining the characteristic vibrations. The size of crystal would affect the modes of vibration only in so far as the unit cells at the surface of a crystal differ from those in the interior. The differences would be of the order of the difference of specific heat as determined with a single crystal and with the same mass of small crystals.

Spectroscopic Data

Whereas the Debye and Born theories lead to vibration frequencies of a crystalline solid giving a continuous spectrum, the Raman theory leads to a line spectrum. The relevant experimental data may be got from studies of the Raman spectra, the luminescence of crystals excited by light or by electric bombardment, and the absorption spectra.

A striking feature of the spectrum of the radiation scattered when a monochromatic beam traverses a transparent crystal is the *sharpness* of the lines of displaced frequency appearing in the infra-red. This feature is characteristic of the lines associated with either extensional or distortional vibrations of the ions or molecules in the crystal lattice or with translational or rotational motions. The latter type fails to appear when the substance is in the amorphous or fluid state, being then replaced by a diffuse continuum. The monochromatism of the vibrations is therefore closely associated with the crystalline state. Two plates are reproduced showing this monochromatism associated with superlattice frequencies for quartz and diamond.

Detailed studies of the relevant data have been made in the Physics Department of the Indian Institute of Science, Bangalore, and are presented in a series of six papers. R. Norris deals with white phosphorus and quartz, B. Dayal with the cubic metals (lithium, tungsten, gold, silicon and grey tin) and with the hexagonal metals (magnesium, zinc and cadmium), V. B. Anand deals with diamond and C. S. Venkateswaran with alkali halides. Good or improved agreement of theory with experiment is found by using the Raman theory instead of the Debye theory. Numerical comparisons using the Born theory appear to be missing. The bulk of the thermal energy is associated with unit-cell frequencies appearing as monochromatic lines in the infra-red. The residue, associated with superlattice frequencies, appears in the remote infra-red, is monochromatic and is relatively important only at low temperatures.

ADVANCE IN INVENTION: ITS RELATION TO WORLD PEACE

By D. CARADOG JONES

University of Liverpool

A YEAR after the outbreak of the present War the results were published of a study of the causes of the failure to preserve peace. The members of the study group are described as mainly officers of international organizations with headquarters at Geneva, meeting unofficially and able therefore to contribute to the discussion without reserve. The publication was issued under the authority of the Carnegie Endowment for International Peace.

World Unity

The factors that led to war are classed under three heads: political, economic, spiritual. But all three, when critically examined, are revealed as a failure to visualize the world as an organic whole. "The most startling example of the collective failure" to take a world view, under the political head, they say "was the attitude adopted toward Germany, not only in the clauses of the settlement, but still more in the manner of their presentation. . . . In particular, the refusal to negotiate with Germany created an attitude of mind in that country that was never subsequently changed." Put the rulers of Germany under restraint; yes. Make the German people suffer; impossible, unless we are prepared ourselves to suffer with them. However much they may appear to our limited vision to deserve punishment, by placing them in the dock we shall but bring judgment upon our own heads. We are reminded of an illuminating analogy due to that far-sighted statesman, Señor S. de Madariaga: "A nation, a limb of the world, misbehaves, i.e., it acts against the world community, which is the whole body. And sanctions are decided on to punish it. But, can we punish a limb without punishing the whole body?" If we sow the wind, we reap the whirlwind.

The fundamental character of this principle of world unity comes out nowhere so clearly as in the economic aspect of international relations. The Geneva group recall the sequence of events following the attempt to extract huge reparations from Germany. Failure to grasp the fact that payment in goods would immediately put large numbers of people in the allied countries out of work may be taken as evidence that the mismanagement of affairs after the War of 1914–18 was due in large measure to a lack of understanding of elementary economics. It was as much a failure of the head as of the heart. Happily there are signs of greater enlightenment among those who are at present responsible for advising the leaders of the democratic Governments in such matters. In particular, they are fully aware of the consequences of the remarkable progress achieved in technological invention. This was causing so great a revolution in industrial production, even before 1914, that it was bound sooner or later to lead to trouble between nations if each attempted to pursue its own self-interested path regardless of the welfare of others; and this new industrial revolution may cause still greater disaster after the present War if its implications are not more widely and clearly realized. It is essential that Governments should be able to depend upon the support of public opinion for any concerted measures they may adopt for the control of output and its distribution, in the interests of the world as a whole and especially of the weaker nations.

Progress in Output

A few facts may be given which bear striking witness to the extent and the rate of advance in the output capacity of modern machinery. Colin Clark has made a comparison of the real income produced per head of the working population in different countries on the basis of a 48-hour week. His figures indicate a rise in Sweden and Japan to a level more than four times as high as that reached seventy or eighty years ago. In most highly industrialized countries the income so calculated has been at least doubled during the same period of years, and this was accomplished in spite of a considerable increase in population and decrease in the hours of work. In the last two decades the rate of progress has been even more astonishing. According to an estimate published by the Royal Economic Society, the increase in physical output per operative in the United

Kingdom, for all industries covered by the Board of Trade Census of Production, was 34 per cent between the years 1924 and 1935 and 27 per cent during 1930–1935. For engineering the corresponding increase, 1930–1935, was 57 per cent; for textiles, 37 per cent.

Even allowing a considerable margin of error in all these figures, there is not the least doubt about their general trend. Moreover, the wide range of invention is as striking as the acceleration in output. The telephone, the motor-car, the aeroplane, the motion picture, and radio have had so far-reaching an influence upon the structure of society—turning almost unknown nations into next-door neighbours overnight—that it is only with a jerk of memory we recall that they are largely the product of the present century. About a million telephones were in use and the motor-car was just being introduced into the United States forty years ago; now the telephone industry is the third largest public utility concern in the country and there is one motor-car for every five people. The aeroplane was regarded with scepticism and the other two inventions were as yet unknown. These facts are mentioned by Prof. W. F. Ogburn in a recent American publication, which directs attention also to the immense and fascinating possibilities the future holds for us, arising out of the discovery of synthetic resins and plastics; rayon, artificial cotton, and wool derived from cellulose; synthetic rubber and wood substitutes; devices such as the photo-electric cell, and many other inventions.

What does all this imply? It should surely imply a fuller and more varied life for all mankind, if only we could agree upon a fair method of sharing the products of hand and brain. There comes the hitch. The new industrial revolution burst upon us unprepared; we all know how a few primary producers were driven in sheer desperation to destroy their surplus stock, after a vain attempt to dispose of the overwhelming output of certain commodities at remunerative prices. Is there no danger that the same conditions will return when this War ends? The urgency of essential war requirements speeds up output enormously and sharpens inventive wit. It is certain, therefore, that the pace and capacity of production of our machines will be very much greater than they were when the War of 1914–18 ceased. Past experience proves, too, that it will be a relatively simple matter to change over from war to peace production. Yet, before this War started, it was estimated that the people of the United States, to take but one example, could subsist if necessary on about one third of their output, leaving the remaining two thirds to be devoted to other purposes. What is true of the United States is true, in varying degrees, of other equally advanced countries.

Problem of Surpluses

This presents the problem of surpluses in a new and significant light. It is clear that under conditions of peace, if our aim is to provide employment for all who are capable of work—since sharing the work available, by a general reduction in the weekly hours of labour, would only be a partial solution of the unemployment problem—the potential supply of many commodities, with full employment, will far exceed the effective demand for them within the country of their origin. What then can the United States, for example, do with her vast surplus? She can only hope to exchange a relatively small part of for the few commodities which she cannot herself produce. As for the rest, she has a choice of four courses: she can destroy it, which no one would commend; she can store it or sell it on long credit, but either of these two courses would only put off the day of reckoning and make the problem more difficult to solve eventually; the one choice left open is to give it away to nations whose need is greater than her own. To put this last suggestion into practice, though at first sight revolutionary, would be entirely consistent with the fundamental principle of world unity, whereby all the peoples of the world are regarded as one people, one family of nations. The average real income per occupied person in the United States has been very roughly estimated at one hundred dollars a month; the corresponding figure in India or China would be equivalent to five or ten dollars at most. There is a like discrepancy between the standard of living among these Asiatic peoples and that which we in Great Britain enjoy, and the difference is a measure of our responsibility towards them. A carefully planned scheme of assistance, covering all aspects of life, would in course of time result in greatly improved conditions in both India and China.

How is such assistance to be given? Let us suppose that, with the return of peace, a time comes when we have in use all the labour we can effectively employ to satisfy our own needs, but that many men are still without work and our machines are not running at full pressure. Manufacturers are unwilling to take the risk of increasing their production, because they anticipate no increase in demand in the home or foreign market at existing prices. There are two courses then open. The Government may maintain these potential workers in idleness, which is bad for everybody concerned. That was the policy adopted after 1914–18. The alternative is to find work for them. India and China are in sore need of tractors and other agricultural implements. They might indeed be able and willing to pay for them with rice, tea, silk and other commodities if the price asked were not too high. But it would be far better for the British Government to make free gifts to these countries than to permit our labour force and our plant to deteriorate by remaining idle. The cost of the creation of any additional credit notes needed would be trifling, and no money is wasted, in the sense of being used up, by circulating it. Contracts would be given to engineering firms in the normal way; they would be paid fair prices and the workmen would receive good wages for the work done. Their increased earnings would result in increased expenditure, bringing extra gain to shopkeepers and others, besides extra revenue to the Government in taxation. It is thus evident that, by helping to raise the standard of living of depressed peoples, our own standard would rise simultaneously. No nation can move forward at the expense of others: we can only advance together—yet another illustration of the organic unity of the world.

International Pool Control

It should be a relatively simple matter, therefore, to accumulate a pool of surpluses of many kinds from Great Britain, the United States and other advanced countries. This pool might be placed under the control of an International Advisory Council, composed of experienced men and women of the highest integrity, capable of taking a world view in the handling of the delicate problems arising between nations. Such a Council, assisted by fact-finding Commissions of economic and other specialists, would command high authority. It would express a reasoned opinion for the guidance of Governments as to the wisest and most just plan for the control of world production and the disposal of surpluses, based upon a judicial and expert examination of all the data available. The relatively rich countries could be credited if they so wished, at agreed nominal prices, with any 'gifts' they contributed to the pool, and these credits would be regarded as giving them a call upon the pool at any future time should they themselves be in need.

It is not too soon to consider the setting up of an Advisory Council now. The judges of the Permanent Court of International Justice, seeing that they have established for themselves a reputation for wisdom and impartiality, might be invited to prepare a scheme for the selection of a panel of suitable people to serve upon it. Plans are already under discussion for the feeding and restoration of the famine-stricken inhabitants of European countries. It is too big a task for ourselves and America alone; all countries should take pride in working together for this purpose. It might well be handed over to such a body as the proposed Advisory Council. The disposal of surpluses and the feeding of the hungry are clearly complementary problems: the solution of the first is the key to the solution of the second.

One fundamental difference is to be noted between this approach to post-war problems and the Conference method adopted after the War of 1914–18. We leave the arena of politics, where each nation has its own ends in view, and become intent upon an objective and scientific task: seeking to satisfy, out of our common store, the elemental needs of all peoples. Upon that sound moral and psychological basis it should be possible to go on to build a peaceful World Order.

METEOROLOGICAL RESEARCH IN GREAT BRITAIN

AIR MINISTRY RESEARCH COMMITTEE

THE importance of meteorology to aviation has necessitated an extension of the State meteorological service far beyond the modest dreams of meteorologists of the last generation. At the present time meteorological forecasting is a vital element in the national war effort, especially in the conduct of the offensive; but the return of peace and the renewed expansion of civil aviation will maintain the need for weather prediction, which also has great importance for agriculture and many other branches of the national economy.

The science and art of weather prediction have made great progress during the present century, but it remains uncertain whether even now all the fundamental factors that determine the weather changes have been discovered, and also whether the programme of observation yet includes all the elements necessary as a foundation for prediction. The problems both of observation and of theory are extremely complicated. It is therefore desirable that, along with the day-to-day application of the knowledge already available, proportionate efforts should be made to improve our knowledge and our methods.

For this reason the Secretary of State for Air has recently appointed a Meteorological Research Committee to advise and assist in the carrying out of meteorological investigations. The Committee is constituted as follows: Prof. S. Chapman, professor of mathematics at the Imperial College of Science and Technology (chairman); Prof. D. Brunt, professor of meteorology at the Imperial College of Science and Technology; Dr. G. M. B. Dobson, reader in meteorology in the University of Oxford; Prof. G. I. Taylor, Yarrow research professor of the Royal Society; the Director of the Meteorological Office; the Director of Scientific Research of the Ministry of Aircraft Production; the Director of the Naval Meteorological Service; and representatives of the Air Staff and civil aviation.

At present the Committee will naturally be concerned chiefly with problems directly concerned with the war effort, and such work must for the time being remain secret, though any incidental results not likely to be of service to the enemy may be published.

The Committee would welcome contact and cooperation with university departments or other institutions engaged on work that bears on meteorology; as a result of inquiries in the United Kingdom, information concerning such work, and offers of assistance, have been received from several universities. Correspondence, which should be addressed to the Secretary, Meteorological Research Committee, Meteorological Office, Air Ministry, Kingsway, London, W.C.2, is invited from any other university or research institutions which can assist in this work.

Co-operation of the Royal Society

The formation of a Meteorological Research Committee by the Air Ministry, announced above, is an important and very welcome advance in the organization of British meteorological research. The Air Ministry Committee will at present confine its work chiefly to those problems which have an immediate practical application and are likely to be solved in a fairly short time. The Royal Society has been invited by the Air Ministry to co-operate with the Meteorological Research Committee by undertaking research on certain aspects of meteorology which, though of fundamental importance for the advance of the subject, may not have an immediate practica application.

The Council of the Royal Society has agreed to this request, and has entrusted the immediate responsibility for the work to the Gassiot Committee. This Committee, first constituted in 1871, was originally appointed to administer the Gassiot and other trust funds applicable to the maintenance of certain British meteorological and magnetic observatories, and to make recommendations as to their work. The terms of reference have now been enlarged to include the supervision of fundamental meteorological research such as has been asked for by the Air Ministry The personnel of the Committee is appropriate for this purpose; the chairman is Dr. G. M. B. Dobson, and the members are Sir Edward Appleton, Profs D. Brunt and S. Chapman, Sir Henry Lyons, Sir George Simpson, Prof. G. I. Taylor, Sir Gilber Walker, the Astronomer Royal, the President of the Royal Astronomical Society, the Director of the Meteorological Office, and *ex officio*, the Treasurer o the Royal Society (Prof. T. R. Merton) and the Secretary of the Royal Society (Prof. A. C. G Egerton).

These arrangements seem eminently suitable because pure fundamental research which may hav to be continued over a long period, and which requires the co-operation of many independent workers in university departments and laboratories, can probably be organized more easily by the Royal Society than by a Government department, however much the latter may be in sympathy with the object of the researches. The Royal Society has already shown its willingness to further such work by appointing Dr. E. Glückauf to a Mackinnon Studentship, to enable him to carry out meteorological research under the general guidance of the Gassiot Committee.

The general research in which the Air Ministry has sought the co-operation of the Royal Society is that of radiation in the atmosphere, with special reference to radiation equilibrium conditions in the stratosphere. It is fairly generally accepted that the average temperature of the stratosphere—as of the warm region above it—is determined by an equilibrium between the energy absorbed, from both the downward solar radiation and the upward terrestrial radiation, and the energy radiated by the air in the stratosphere. Observations have shown that there are large variations of temperature in the stratosphere both with time and with place, but we know little as to why such variations occur. Few meteorologists, for example, would care to be dogmatic as to why the stratosphere is some 50° C. *colder* in equatorial regions than in polar regions.

The principal gases of the atmosphere are mostly very transparent to radiation, and the radiative conditions are largely governed by such minor but polyatomic constituents as water vapour, carbon dioxide, ozone and possibly others. To understand the radiation equilibrium in the atmosphere, it is necessary to know (*a*) what gases are present which have important absorption bands for radiation; (*b*) in what proportions they are present at different levels; (*c*) how gases such as ozone are formed and decomposed; (*d*) the absorption coefficients of these gases for different wave-lengths, and whether the absorption and emission spectra have a continuous or fine line structure. Finally, when the above facts are determined, it will be necessary to calculate the radiation equilibrium temperatures at different levels and to determine how rapidly the temperature will change when the conditions alter.

The Gassiot Committee has been fortunate in enlisting expert help in particular branches of the subjects involved, and has formed three sub-committees to deal with different aspects of the above question. It is hoped in this way that the available relevant knowledge will be collected, and that those questions which require more experimental work may be defined, so that arrangements can be made for the work to be done, so far as this should prove possible under present conditions.

Dr. G. M. B. Dobson is the chairman of Sub-Committee A, which will deal with the chemical analysis and the observation of the amounts of the polyatomic constituents of the air at different levels; other members of this sub-committee are Profs. H. Dingle and F. A. Paneth, and Dr. E. Glückauf.

Sub-Committee B will deal with the photophysics and photochemistry of the atmosphere, from the highest levels downwards, and, in particular, with the changing equilibrium of ozone and any other variable polyatomic constituents; the chairman of this sub-committee is Prof. H. W. Massey, and the members are Prof. K. G. Emeléus, Dr. W. C. Price, and Dr. J. Sayers.

Sub-committee C will consider the radiation balance in the atmosphere; its chairman is Prof. S. Chapman, and its members are Prof. D. Brunt, Dr. G. S. Callendar, Dr. T. G. Cowling, Dr. A. R. Meetham, Sir George Simpson, and Dr. G. B. B. M. Sutherland.

There will be few who will not agree that the first meteorological problem thus selected for attack is a very important one, and still fewer who will dispute its difficulty. It is hoped that the scientific effort which the Royal Society can bring to bear on this work will lead to substantial progress. The Gassiot Committee is aware that at laboratories and institutions in many parts of the world work has been undertaken that bears on these problems, and the Committee would welcome co-operation in cases where the continuance of such work is possible in present circumstances.

SCIENCE AND TECHNOLOGY IN THE SOVIET UNION

SCIENCE and technology in the Soviet Union was the subject of the first of the two symposia held over the Easter week-end by the Faculty of Science of Marx House (Marx Memorial Library and Workers' School) at the London School of Hygiene and Tropical Medicine. Prof. J. B. S. Haldane presided and nine speakers took part in the two sessions. The second session, on Race and Fascism, was dealt with in Nature of April 18, p. 426.

Prof. J. D. Bernal spoke on physical science in the U.S.S.R. A great deal of fundamental work has been done in the Soviet Union and many difficulties have been overcome. In 1920 there were only forty trained physicists in the whole country, but by 1934 in the big institutes in Leningrad there was a six years course which was more rigorous than that in the Cavendish Laboratory. Since then tens of thousands of physicists had been trained. Physics played a vital part in the general plan of development and in the preparations for the expected attack on the country.

As an example of the manner in which the fundamental problems studied arose from the needs of Soviet economy, Prof. Bernal took the transmission of electric power. Power losses which were trivial in Britain became serious because of the great distances in the Soviet Union. The properties of insulators had to be studied and this required fundamental work on the passage of electricity through crystals and on the quantum theory of the solid state. In the metal industry, also, problems arose which led to a rapid development of crystal physics under Joffe and to the working out of a dynamic theory of plastic deformation. Rehbinder's discovery that the hardness of metals varies according to the surrounding medium is a fundamental one and has already led to changes of technique in dealing with metals.

Science is planned in the U.S.S.R. as a part of economy as a whole on the basis that, statistically, the results will be proportional to the effort applied in any particular field. Only the general requirements are given from outside, and the Academy of Sciences works out in general where the main lines of attack should be made. Each group of workers in each laboratory settles its own problems of how to go about the work. To-day the whole of Soviet science has been turned to the job of winning the War, to the problems of the production and use of new weapons, to the reorganization of industry in new areas, and to the discovery of new materials and sources of supply. The present lack of contact between Soviet men of science and those of other countries is very much to be deplored, and knowledge of what they are doing would help us to realize in a rational way the possibilities of science for a new civilization.

Mr. H. P. Vowles, speaking on electrification in the Soviet Union, said that Lenin, with his genius for applying Marxist theory to a concrete situation, realized very early that the new Soviet State would be menaced from within as well as from outside so long as small-scale methods remained the dominant mode of production. He realized that it would be impossible to build up large-scale production without electrification, hence his well-known saying that in Russia "Socialism was the Soviet Power plus Electrification". On Lenin's initiative the Commission on Electrification known as GOELRO began work and soon achieved the first success of the new State in industrialization.

Mr. Vowles stated that, although the United States still leads the world in output per capita of electricity, the Soviet Union has drawn level with that country in many features of electrification and has surpassed it in rate of electric development, in the development of heat and power stations, in the mechanization and electrification of agriculture and in the correlated planning of production and consumption of electricity. The United States originally took its engineering technique from Britain, but from 1850 Britain drew increasingly on American technology and skill. The Soviet Union has been greatly indebted to the United States for the technique of power production, but already after the short period of twenty years the Americans can learn much from Soviet electrification.

Dr. N. F. M. Henry discussed the part of geology in Soviet economy. He showed that although there were a few geologists of international standing in Tsarist Russia, less than 1 per cent of the vast area of the empire had been mapped on a scale of ¼-inch to one mile. From the beginning, the Soviet Government paid special attention to geology because the fundamental position of this science in the building of a socialist economy was realized. The electrification and industrialization of the country urgently demanded coal, iron and large supplies of many other mineral substances. Because of the great distances involved it was of vital importance to develop mineral supplies in many parts of the country. It was impossible to survey the 8 million square miles of the Soviet Union square by square as was done in Britain over a period of a hundred years. Soviet geologists were faced with a double problem of teaching thousands of young geologists and of developing geochemical theory as a guide to the rapid study of the most suitable areas for mineral exploitation. The mineral output of the Soviet Union to-day is evidence that these big problems were tackled with energy and with very good organization. It is no accident that Soviet men of science should lead the world in geochemistry, for its development was urgently demanded by the needs of Soviet economy.

In 1936 the total amount spent on geological work was 1,000 million roubles (about £38,000,000), but in March 1938 it was officially stated that this was to be doubled. The permanent scientific staff of the Central Institute for Geology numbers 500, but the total number of geologists and prospectors working under its control is about 10,000. These figures show the importance of geology to the Soviet Union, and this importance is reflected in the tremendous public interest in the subject. Millions of school-children study it in the field and in the laboratories of the Pioneer Palaces. The man in the street often reads of the latest discoveries, and the leading geologists are public figures.

Mr. H. Rose spoke on aspects of Soviet developments in chemical engineering, dealing in particular with the underground gasification of coal and with the Soviet rubber industry. While proposals for the underground gasification of coal were first made many years ago by Mendeléeff, and by Sir William Ramsay who actually carried out trial bores in Great Britain, it was Lenin who first paid serious attention to the possibilities opened out by this revolution in technique. In 1937 experimental shafts were sunk, after much careful preparation, in the Donbas. The successful development on a wide scale which was begun in 1940 was made possible by the work of Kapitza, who recently received a Stalin Prize, on the low-pressure liquefaction of air, because a cheap supply of oxygen is required to improve the quality of the gas.

The social and economic implications of this new development are of tremendous importance, for one man can now do the work of ten miners. Mr. Rose believes that technical developments in steel blast furnaces will probably do away with the need for mining coal even for metallurgical coke, and then in the Soviet Union the hard and dangerous occupation of underground coal mining will disappear completely.

Although scientific men such as Kondakov and Lebedev, working under the old regime, made considerable contributions to the early study of rubber, it was not until after the Revolution that this study developed enormously and led to the production of synthetic rubber on a large scale from 1931 onwards. To-day the Soviet Union is probably the largest producer of synthetic rubber in the world, and 80 per cent of her requirements are now satisfied by the synthetic product. In addition, the rubber problem is being solved by the rapid development of the natural rubber-yielding plants Kok-Sagyz and Tau-Sagyz.

Dr. M. Ruhemann dealt with low-temperature research and development. He spoke in particular about the separation of natural and industrial gases, which necessitates the use of low temperatures and refrigerating machinery. The studies of Soviet scientific workers on the phase equilibria of different gaseous mixtures and of the solid-liquid mixtures of several binary and ternary systems are now well known. These findings were applied to coke-oven gas, and important results were soon obtained, such as the extraction of hydrogen of 97 per cent purity and the development of a new method of obtaining krypton. As a result of this scientific research, the Soviet Union now has a larger gas separation industry than any other country in the world, and this is of great importance for the heavy chemical industry.

The afternoon session was opened by Prof. J. B. S. Haldane, who spoke on the biological sciences in the U.S.S.R. In biochemistry, work has been done on the way in which a protein 'gets itself copied', and the emphasis has been on the study of processes rather than on the isolation of substances. In sheep genetics the Soviet Union is well ahead, and the beginnings of a chromosome map for sheep are now visible. New species of plants have been produced, such as an octoploid wheat, and the great work of Vavilov on the systematics of cultivated plants has led to the development of types suitable for many parts of the vast territory.

Umanski's discovery that cancer tissue will act as an organizer is very important, and work is proceeding on the study of the conditions necessary for tissue to be capable of being organized. In medical techniques several advances have been made. The transfusion of cadaver blood is a regular procedure now, and it has been found that it is more effective than blood from living donors, although the reason for this is not yet known. The grafting of tissues from corpses was based on the idea that the distinction between life and death and between different organisms is not so fundamental as has been thought. By the use of such processes, Filatov and his assistants have probably restored sight to more people than all other surgeons in the world put together.

Soviet biology is linked not only with agriculture, but also with the development of fishing, hunting, the timber industry, and very closely with medicine. Nevertheless, it does much work of fundamental importance which is altering our theoretical approach to many biological problems.

Mr. J. L. Fyfe made a contribution on the genetics controversy in the U.S.S.R. In his opinion the clash between the geneticists and Lysenko, a physiologist, arose because of the close relation between science and technical needs. Vernalization is the opposite of plant-breeding in the sense that it is designed to produce improved forms of crops by treatment, not to select them by testing. The special importance of vernalization in the Soviet Union is its speed as compared with plant-breeding. In 1931 Stalin said that the Soviet Union was fifty or a hundred years behind the advanced countries, and he gave the country ten years to make up leeway. Prejudices have obscured the issues, and this controversy has developed in a period of strong anti-Soviet propaganda. Mr. Fyfe went on to discuss the relation between genetics and the ideas of Lysenko. These ideas are in many ways contradictory to the basic postulates of genetics, but it is significant that recent developments in genetics itself are doing very much the same thing. Genetics is thus approaching a crisis, and the work and ideas of Lysenko are contributing to this developing crisis. The crying need, however, is for careful experimental work to test the theories of Lysenko, for it would be as foolish to set him up as an infallible prophet as it is to dismiss his work lightly.

Mrs. Beatrice King spoke on science in Soviet school education, which, she said, can only be understood in its social and economic setting. In the struggle of an economically backward country to transform itself in a few years into an advanced one through the building of a socialist economy, science has been of prime importance. In education, also, the Soviet Union has passed through a period of intense struggle to become an advanced country and to develop among the people the scientific outlook which is essential for the building of socialism.

In school the approach is historical and international, and science is directly linked with social and economic problems so that children learn at an early stage to think scientifically and not to regard science as a separate subject. All children study scientific subjects experimentally as well as theoretically, but there is no specialization in ordinary schools. The text-books which are used in schools and in universities are generally the work of several writers and are always tried out for a year before being finally approved.

Outside school, science plays a large part in the lives of the children. Science and scientific discoveries bulk largely in the literature of children of all ages, while their plays and films often have scientific subjects. The children's Pioneer Palaces always have laboratories, and school science and exploration clubs flourish, while excursions to the country and to museums and regional-study holidays are attended by millions of children every year.

Dr. M. Ruhemann spoke on the scientific worker in Soviet society. Soviet men of science have closer contact with other strata of the population than is the case in Western countries, and they react to the pressure of public opinion from a people which has learned to respect science and to expect a lot from it. In most cases students receive a stipend from the State during their five-year course. The best students can proceed to do research work with increased stipends and are entitled to all the help that their seniors can give them. As a member of the same trade union as all other employees in the institution, whether technical, scientific or office workers, the man of science becomes bound up with the life of the institute. The intense Soviet life around, the unlimited scope for solving practical problems, and, finally, the basic Marxist conception of science as the foundation of technique and of the development of the productive forces of society make the scientific worker a conscious and enthusiastic citizen.

The whole symposium was attended by about 250 people, and Marx House is to be congratulated on the organization of such a successful set of meetings. These symposia constitute a valuable contribution to Anglo-Soviet unity and understanding.

THE SCIENTIFIC WORK OF ELIE METCHNIKOFF

By DR. G. F. PETRIE
Lister Institute

THE heightened interest in the cultural and intellectual activities of the U.S.S.R. has stimulated a desire to know more about the work of outstanding Russian men of science who belong to the recent past, and thus the anniversary of the birth of Metchnikoff on May 16, 1845, is a fitting time to survey his achievements and to indicate the significance at the present day of his fundamental work on the role of phagocytosis in inflammation and immunity.

Metchnikoff's training as a zoologist was of the greatest value to him throughout his life in guiding his researches, and indeed in consequence of it he was led to the central point of his theory of immunity, for during his stay at Messina in 1882 he made his observations on the mobile cells of a transparent starfish larva and conceived the idea that similar cells might serve to defend the organism against intruding particles whether these were living or non-living. A simple experiment carried out on the spot went far towards establishing the proof. As he himself wrote: "A zoologist until then, I suddenly became a pathologist." During the next twenty-five years the theory was extended by Metchnikoff and his pupils and by numerous workers in many parts of the world to include bacterial infections such as anthrax and erysipelas, with the result that ample evidence of the importance of phagocytosis as a means of disposal of intrusive bacterial elements was forthcoming.

Metchnikoff was fortunate in his choice of scientific associates and of the milieu in which his life-work was done. On his first visit to Pasteur in 1887 he was kindly received and was offered a laboratory in the then newly built Institute in the Rue Dutot, whereas, soon afterwards, Koch in Berlin and Emmerich in Munich gave him such a cool reception that he decided to accept Pasteur's offer, and thus in October 1888 he entered the most fruitful period of his career, which lasted until his death in 1916 at the age of seventy-one.

The controversies on the rival doctrines of immunity upheld by the French and the German schools—which, on one side at least, gave the impression of national partisanship—are now of merely historical interest. The humoral theory to which the German workers obstinately clung was based on the direct bactericidal action of the blood-serum of normal and, in particular, of immunized animals. The view now held is that active phagocytosis depends upon sensitization of the bacteria by bacteriotropic substances that are present in normal and immune sera. The two points of view are thus by no means mutually hostile; they are indeed complementary and their relative importance varies with the particular instance of an infective process that is chosen for illustration. After Metchnikoff's death, Aschoff and other workers systematized the cellular theory of immunity by defining the types of cells scattered throughout the tissues and organs of the body that are capable of functioning as phagocytes; these form the so-called reticulo-endothelial system of cells. This scheme of classification has conduced to precision and convenience of description. Recent studies of phagocytosis have been numerous and have been directed towards elucidating the finer mechanisms of the process as revealed by physical and physico-chemical methods. The romantic attribution to the phagocytes of purposeful activities as defenders of the citadel of life against bacterial invaders, which so impressed the popular mind in the last decades of the nineteenth century, has given place to more prosaic interpretations. Experimental work has thrown light on such problems as the part played by the nature of the surface of the particles exposed to phagocytosis; the influence of the *p*H of the surrounding medium upon the exposed particles and upon the phagocytes; the influence of temperature, of surface forces, and of the viscosity of the cell protoplasm upon the intake of particles; and the differences that are observed in the functional activity of leucocytes when these are collected from healthy and diseased subjects.

Metchnikoff's researches included studies on the comparative pathology of inflammation, a process in which phagocytosis is one of the chief manifestations. His observations on chemotaxis and on intracellular digestion of bacteria engulfed by the phagocytes have not been disturbed by the newer knowledge. There still remains, however, for solution the refractory problem of the deviations from the normal of the biochemical activities within the local phagocytes and fixed tissue cells; these changes must be assumed to vary both in quality and degree throughout the phases of the inflammatory process until the lesion has healed.

The general interest aroused by his work on the transmission of syphilis to chimpanzees and on the prophylaxis of the experimental disease by the inunction of mercurial ointment is still remembered. Metchnikoff had a passion for probing into the mysteries of life and death, as is shown by his own mental reaction to his approaching dissolution, but it would seem that in his views on the production of senile changes in the tissues caused, as he thought, by intoxication from harmful intestinal bacteria, his imaginative powers outran his judgment; the habit of drinking sour milk as a preventive measure against ill-health and premature old age has now disappeared. Nevertheless, his work has encouraged the important study of the physiology and pathology of senescence, and within recent years this subject has engaged the attention of an enthusiastic group of scientific workers in the United States and also in Great Britain.

Metchnikoff was international in outlook both as a man of science and as a humanist, and here it is worth quoting a sentence from the warmly expressed tribute of Emile Roux, his friend and colleague, on the occasion of Metchnikoff's seventieth birthday. "Resté Russe de nationalité, vous êtes devenu Français par votre choix et vous avez contracté avec l'Institut Pasteur une alliance franco-russe, longtemps avant que les diplomates en aient eu l'idée."

Is it, perhaps, too fanciful to believe that the far-reaching speculations of Metchnikoff were influenced by the early impressions which he formed when as a boy he viewed with the eyes of a born naturalist the boundless steppes that surrounded his village home near Kharkoff? He can never lose his place among the company of the pioneers of experimental medicine.

Dr. B. M. Griffiths

DR. B. MILLARD GRIFFITHS, who died on March 25, was born at Kidderminster in 1887, and studied at the University of Birmingham during the years 1905–8; he took the D.Sc. degree of that University in 1923. Towards the end of the War of 1914–18 he was assistant to Prof. Yapp at Belfast, but in October of 1920 he was appointed lecturer at Newcastle and afterwards, in 1924, became reader in charge of the new botanical laboratories established at Durham, which he placed upon a secure footing.

His early work concerned the giant bacteria belonging to the genus Hillhousia and was carried out in conjunction with G. T. West, but most of his scientific investigations related to the Algæ. Already in 1912 he published a paper on the Algæ of Stanklin Pool and in 1915 a morphological study of Glaucocystis, while afterwards he turned his attention chiefly to planktonic and limnological studies. We owe to him a considerable number of data on the phytoplankton of the lowland pools of Britain contained in a number of papers published in the Linnean Society's Journal.

He took some part in the foundation of the Freshwater Biological Association and for several years represented the University of Durham on its Council. During the later years of his life he suffered much from ill-health, and this no doubt contributed materially to reduce his output of scientific work, which showed considerable promise.

F. E. FRITSCH.

NEWS and VIEWS

Grassland Research in Great Britain

Sir George Stapledon, C.B.E., F.R.S.

THE appointment of Sir George Stapledon as the director of the Ministry of Agriculture Grassland Improvement Station, Dodwell, marks a break in a long period of pioneer service which may be said to have revolutionized the current methods of grassland management. After holding the posts of professor at Cirencester and adviser in agricultural botany at Aberystwyth, Sir George became the first director of the official Seed Testing Station when it was founded by the Food Production Department of the Ministry of Agriculture during the War of 1914–18. Thence he proceeded to the chair of agricultural botany at Aberystwyth and also became director of the Welsh Plant Breeding Station when it was founded in 1919. Gathering round him a band of enthusiastic and patient research assistants, he began the long series of experiments which have made his work famous the world over.

So early as 1913 Sir George was interested in pasture problems, such as drought resistance, and the response of grassland species under manuring, and in 1916 he collaborated with his present successor T. J. Jenkin in investigations on indigenous species in relation to habitat and sown species. For the next twenty-five years his attention was devoted to the various ways in which the grasslands of Great Britain could be improved and better use made of the great acreage of unprofitable and neglected pastures up and down Great Britain. The importance of varieties and strains was fully recognized, and geneticists and plant breeders on his staff concentrated their attention on the production of the special types of the herbage plants needed for specific purposes. The labour involved was immense, and only by most skilful organization has it been possible to carry through the work without confusion or delay, and to apply the results to agricultural practice. Varieties of grasses and clovers have been bred for earliness or lateness, for leaf or stem production, for spreading or erect types, to provide seed to meet different requirements.

Parallel with the plant-breeding work, problems of management were investigated, particularly in relation to the effects of grazing, and the most amazing and valuable results were obtained. But all the time Sir George was working towards his main object of obtaining recognition from the Government and farmers alike that poor or derelict pasture could be so improved as to become an important asset instead of a liability. Much preliminary critical work was carried out, the importance of buried and viable seeds in the soil being early recognized. Then in 1933 the Station acquired Cahn Hill, whereon large-scale hill experiments could be made in order to develop methods whereby improvements could be made and to determine their economic value. Much progress has been made, both on the hill pastures and in connexion with ley farming, in which poor permanent pasture is improved by ploughing up and reseeding. Sir George Stapledon's new appointment will provide an excellent opportunity to demonstrate the value of his ideas, backed by wide experience, and the venture will be followed with great interest by all who have the interests of agriculture at heart.

Dr. T. J. Jenkin

DR. T. J. JENKIN, who succeeds Sir George Stapledon at Aberystwyth as professor of agriculture and as director of the Plant Breeding Station, has been associated with the Station from its very early days, and prior to that was adviser in agricultural botany at the University College of North Wales, Bangor. At this time he also worked on seed testing and collaborated with Sir George Stapledon. His early work at Aberystwyth included rust resistance trials with wheat, but his attention was soon concentrated on the genetics and breeding of grasses, of which work he was in charge. For years he has devoted himself to the varied aspects of grass improvement, including the problems correlated with self- and cross-fertilization in the more economic species, carrying on comprehensive experiments in connexion with the artificial hybridization of grasses. His work on inter-specific and inter-generic crosses with the grasses opens up many possibilities for the future of grassland improvement.

The valuable results obtained during the comparatively short space of a quarter of a century are eloquent of painstaking and accurate concentration on a multiplicity of details, involving great personal sacrifices of time and leisure. The appointment of Dr. Jenkin as successor to Sir George Stapledon ensures that the best traditions of the Plant Breeding Station will be carried on by one who has himself done much to build up the esteem with which the work of the Station is regarded.

Agricultural Advisers in Washington and London

THE growing importance of agriculture, both in national and in international affairs, has in recent years necessitated certain changes in diplomatic and consular representatives. Denmark, Norway, Sweden and Holland have long had agricultural councillors attached to their consulates in London; men of high distinction such as Mr. Harald Faber, Mr. van Rijn, Mr. I. Bagge (to mention only past officers) and others whose pre-eminence in their subject caused them to be greatly respected by experts in Great Britain. The United States has now appointed an agricultural adviser, Mr. Loyd V. Steere, who has already had some years of service in Berlin, so that he is thoroughly familiar not only with American but also with Continental conditions. Mr. Steere will be cordially welcomed by British agriculturists.

The British Government has now decided to appoint an agricultural expert to its Embassy at Washington and has selected Prof. Scott Watson for the post. The choice will give universal satisfaction. Prof. Scott Watson has an unusually wide knowledge of the subject and of the persons concerned with it. He holds the Sibthorpian chair of rural economy in the University of Oxford, is a member of the Agricultural Research Council and the Agricultural Improvement Council; he is also editor of the Royal Agricultural Society's publications, and is a well-known broadcaster.

Scientific Direction of War

RECENT correspondence in the Press on the direction of war strategy, to which reference is made in the leading article on p. 531 of this issue of NATURE, has had a sequel in the form of a discussion in the House of Lords on May 5. Lord Denman directed attention to the White Paper on Organization for

Joint Planning recently issued, and said there is a considerable amount of dissatisfaction among technical and engineer officers regarding methods of applying equipment to the Army. "We have men of great scientific ability, great technical experts, good factories and workshops, and skilled craftsmen and mechanics, but we need to make sure that they are being utilized to the best advantage." There should be a chain of technical responsibility from the Army Council down to the units in the field. Viscount Swinton also emphasized that we have the men of ability needed in the various fields, but found fault with the present system of utilizing them. Lord Milne said that the "great necessity at the present moment is a scheme to link together our great advantages in technical science with our requirements in military strategy".

Lord Hankey, who has until recently been much concerned with the co-ordination of resources of man-power in different fields, pointed out that the White Paper shows that great advances have been made at least in the lower stages, in the provision for collaboration, but there is room for further improvement, particularly at the ministerial stage. He expressed the hope that it would be possible to add a scientific staff to the Joint General Staff. "Each of the Service Departments is already using scientists, and has found them of great value for operational and other purposes. It is obvious that they should also be brought into the central control of the war." This reminds one of the attitude taken by Sir Henry Tizard in his address at the annual luncheon of the Parliamentary and Science Committee (see NATURE, Feb. 7, p. 164). He divided the scientific effort in relation to the War into two portions: the tactical and the strategical. With regard to the former, he said that in Great Britain we have nothing to fear from any nation; but the latter is not nearly so sound. The remedy, he said, is "to have scientists working side by side and in the closest collaboration with those who have the administrative and executive responsibility". The weight of opinion, scientific and lay, is clearly on the side of increased participation of science in the strategy of the War.

School Medical Service in War-time

IN a Chadwick Lecture delivered on May 12, Dr. J. Alison Glover, late senior medical officer, Board of Education, discussed the school medical service in war-time. In the thirty-one years between the inauguration of the school medical service and the outbreak of the present War the service passed from ascertainment and treatment to prevention, and is entering into a fourth phase, the search for "positive health", the appreciation "that it is the legislator's task to frame a society which shall make the good life possible" and so enable every child to reach the highest degree of health and development of which he is inherently capable. These phases are well shown in the changing outlook on nutrition, from the ascertainment and treatment of malnutrition to the striving after optimum nutrition. In this period of thirty-one years, the British school-child has undergone a wonderful metamorphosis for which, though many other factors have had a share, the school medical service has been largely responsible. The school-child of 1939 was bigger, more resistant to disease, cleaner and in every way fitter to stand the strain of total war than his predecessor of 1908.

The present health of the school-child after two and a half years of war is shown to be well maintained whether it be judged by clinical assessment of nutrition, average measurements of growth, the incidence of infectious and catarrhal diseases, the incidence of neurosis or the general impression of medical men, nurses or teachers closest in touch with school-children. Much vigilance is, however, necessary. The difficulties which the service encountered from evacuation naturally differed in the reception and evacuation areas. They were increased by the constant ebb and flow of the ceaseless 'drift-back', by the interruptions of alerts, by shelter life, appropriation of schools for other purposes, and by the calling up for service with the Forces of medical men, dentists and nurses. The great development of the provision of meals and milk, the intensive campaign for immunization, the conversion of the camps provided by the National Camps Corporation into residential schools, and the great development of the provision for children under five years were also described. Despite some inevitable curtailment the service has continued to render efficient service.

The Association of Scientific Workers

THE twenty-fifth annual council meeting of the Association of Scientific Workers was held during May 2–3 at the London School of Hygiene under the chairmanship of the president, Mr. R. A. Watson Watt, F.R.S. About two hundred delegates, representing the eighty-four branches into which the membership of almost six thousand is divided, attended the Council. In his opening address Mr. Watson Watt spoke of the remarkable growth of the Association especially since its registration as a trade union, and its affiliation to the T.U.C. Referring to the Conference on "Science and the War Effort" convened by the Association in January last, he said that in spite of the success of that Conference it is necessary to persist if the criticisms made then of the misuse of science in the national effort are to result in practical action.

If any fears have been felt that the remarkable growth of the Association in the trade union field was likely to have diminished its concern to maintain the highest scientific standards, these were set at rest by a number of forceful speeches insisting that the two sides of the Association's work must proceed hand in hand, and resolutions confirming this attitude were carried by an overwhelming majority. Reports were given of the successful action taken by the Association to maintain standards of payment and working conditions in industry, and of the activities of committees dealing with science education, medical services, agriculture, and the proper use of refugee scientific workers. A report was also given of the activities of branches in the work of building up an appreciation of science and scientific method among the general public.

Academy of Sciences of the U.S.S.R.

PROF. V. KOMAROV has been re-elected president of the Academy of Sciences of the U.S.S.R.

At the concluding session of the general meeting of the Academy at Sverdlovsk on May 8, the following were elected honorary members: Prof. W. B. Cannon, George Higginson professor of physiology at Harvard Medical School; Sir Henry Dale, president of the Royal Society; Prof. J. B. S. Haldane, Weldon professor of biometry at University College, London; Prof. Ernest O. Lawrence, director of the Radiation Laboratory, University of California; and Prof. Gilbert Newton Lewis, professor of chemistry and dean of the College of Chemistry, University of California.

The Problem of the Autonomy of Life

Prof. F. G. Donnan's review in Nature of April 11 of my book "Science versus Materialism" embodies a few statements about order, organization and energy which ought not to pass without a challenge. He speaks, for example, of "the potency for producing order residing in the disequilibrium between the 'hot' radiation of the sun's photosphere and the relatively cool surface of this planet". Can a scientific man really believe that the difference in temperature between two surfaces (for this is all this statement amounts to) has a potency for producing order ? The remark reads like a parody of present-day fashionable philosophies. Again, Prof. Donnan speaks of the "sun's enormous store of 'organized' energy", and one is bound to ask what his criterion of organization is, and for what reason he considers the energy in the sun to be more organized than energy elsewhere ? Later he speaks of "this disequilibrium (and consequent potency for producing order)". This remark is made with special reference to "the part played by the electro-magnetic field and electro-magnetic radiation". So Prof. Donnan really does seem to believe that disequilibrium can by itself produce order, and that electro-magnetic phenomena have special virtues and accomplishments, such as powers of organization and orderliness.

The truth is, of course, that mere difference in temperature, mere radiation, mere disequilibrium, mere electro-magnetic fields, may be described as the cause of *changes*. Such changes may be ordered if there is something to guide the particles taking part in the change, but they will not be ordered if there is nothing to provide guidance, selection, control, discrimination. When we observe order or organization we have, therefore, to seek for two combined causes: the first is the source of energy, which is usually easy to find, the second is the source of the discrimination. This presents a formidable problem in science. It does so, for example, when we seek to understand the structure of living substance. It is poor science to evade this problem as Prof. Donnan wishes to do.

The *reductio ad absurdum* of Prof. Donnan's view of the potency of temperature differences and radiation would be the assertion that a number of nuts and bolts, connecting rods, piston rings, and other machine parts, would, by nothing more than sufficiently violent kicking, become a complete motor-car, and that this would not happen by chance once in a way, but as often as similar living forms are to be found.

Reginald O. Kapp.

University College,
London.

In his extremely interesting review in Nature of April 11 of "Science versus Materialism" by Prof. Kapp, Prof. F. G. Donnan seems to be playing into the hands of the metaphysicians when he describes radiant energy as a "non-material entity". From his opening paragraph, Prof. Donnan would appear to accept as a definition of 'materialist' one who regards all phenomena, whether pertaining to living or non-living things, as solely explainable in terms of "the existing concepts and laws of physics and chemistry". Certainly his rebuke of Prof. Kapp for suggesting that a non-material something else supports the assumption of a "doubly determined" pattern of life, is consistent with such a definition.

The only logical conclusion to be drawn from the findings of modern physicists is, in my opinion, that electro-magnetic radiations are, *au fond*, just as material as atoms. Physicists used to define matter as "that which affects the senses"; light, for them, was an "imponderable". But a light-wave acts on sense-organs as truly as a sound-wave or a kick on the shin. Either an electro-magnetic wave-train is of a material nature with properties investigable only by physico-chemical means, or it is not. If, as Prof. Donnan seems to imply, light radiation is 'non-material', what concept are we to form of it ? There is only one antonym to the word 'material' that does not involve tautology, and that is 'spiritual', and to state that an entity is not of a material nature is to state that it is of a spiritual nature.

May I mention some findings of recent physicists that appear to me to militate against excluding radiations from the sphere of materiality ?

(1) The fundamentals of matter (protons and electrons) behave, according to circumstances, as waves or particles; but the fundamentals of radiations (photons) likewise have both particulate and undulatory characteristics.

(2) Energy is transferable from atoms to radiations and from radiations to atoms.

(3) Mass and radiation are mutually convertible; thus, the total mass of the separate components of an atomic nucleus is not equal to the mass of the nucleus, but to that mass *plus* the 'energy of binding'. Again, in the hot interiors of the stars matter is steadily being transmuted to electro-magnetic radiations, and, according to Millikan, there is probably occurring in inter-galactic space a complementary synthesis of radiations into matter.

(4) When an electron collides with a photon, the former moves off in one direction with changed velocity; the photon proceeds in another direction with lower energy (longer wave-length and decreased frequency) but with the same velocity. Despite the modification of each entity, the combined momenta remain constant.

(5) One piece of matter can press on another; but radiations likewise exercise pressure on matter.

(6) Atoms have weight, but so have radiations, a weight "as real", says Sir James Jeans, "as a ton of coal". Like the apple, radiations are influenced by a gravitational field, and are "attracted" by a mass of matter.

These examples, which are platitudes to Prof. Donnan, are only brought forward to support my contention that an 'immaterial' entity cannot act upon, or be acted upon by, a 'material' entity, and neither can be begotten of the other. Finally, the very expression 'immaterial entity' is surely a contradiction in terms. If it is not, some new definition of 'non-material' that side-steps 'spiritual' is required.

Charles M. Beadnell.

Hollywood,
Egham Hill,
Egham,
Surrey.

MY expression "potency for producing order" means *potential availability for the occurrence of greater order (that is, decrease of entropy) in another system.* It is no part of my business to enlighten Prof. Kapp on the principles of physical science, but I may perhaps help him by quoting a passage from the writings of a world-famous physicist[1]. "In individual sections of the universe, or in definite material systems, the movement may well be towards a higher degree of order, which is made possible because an adequate compensation occurs in some other systems. Now, according to what the physicist calls 'order', the heat stored up in the sun represents a fabulous provision for order, in so far as this heat has not yet been distributed equally over the whole universe (though its definite tendency is towards that dispersion), but is for the time being concentrated within a relatively small portion of space. The radiation of heat from the sun, of which a small portion reaches us, is the compensating process making possible the manifold forms of life and movement on the earth, which frequently present the features of increasing order."

I must apologize to Prof. Schrödinger for having attributed the expression "organized energy" to him. What he meant was, of course, that the "hot" sun and the "cool" earth represent a *non-equilibrium* distribution of energy, which makes possible the occurrence under suitable conditions of an increase of order (diminution of entropy) on the surface of our planet. It is, of course, quite true, as indicated by my expressions "potency", "potential availability", and Prof. Schrödinger's expressions "making possible", "made possible", that the purely general thermodynamic argument provides only a *conditio sine qua non,* that is, a necessary but not a necessary and sufficient condition. It is this gap which affords a loophole for the metaphysicians (including metaphysically minded engineers), to insert their "entelechies" and "specifications", which are obviously nothing else than words inserted into the description for the purpose of satisfying the personal wish for a mystical element of "causality".

Science, as is seen in the work of the photochemists, biochemists and physiologists, does not proceed in this manner, but endeavours to fill the gap between necessary and sufficient by patient and detailed experimental investigation. I think it would do Prof. Kapp a great deal of good if he could spend some of his spare time in the study of photochemistry and photosynthesis. He would be surprised to find that the relatively high-frequency photons which enter the green leaf do not "kick" the "nuts and bolts" about after the fashion of the mad engineer depicted in his letter. That dramatic scene provides us indeed with a very revealing picture of Prof. Kapp's conceptual "chaos". On the contrary, he would find that the available energy of the "non-equilibrium" photons is largely utilized, by means of the leaf pigments and an enzymatic system, in producing a greater degree of order, not of disorder.

Finally, let me say, as I briefly indicated in my review, that I do not wish to deny that biological science may or will require for its more highly developed autonomous description concepts, methods of thought, and mathematical techniques which are unknown (or at least very unfamiliar and unusual) in present-day physics and chemistry. It may be necessary, for example, to distinguish between the biological concept of 'organization' and the physical concept of 'order', perhaps defining the former as a capability for producing order *for an end.* Needless to say, the teleological or finalistic element in such a definition has been anathema in physical science since the days of the Renaissance and the breakaway from medieval Aristotelian scholasticism. But an autonomous description of biological phenomena amounts to the assumption that such a description will be different in some respects in type from that hitherto found suitable for physical science. If so, it will require an appropriate mathematical technique or a method of symbolic logic involving some sort of 'dimensional' extension in its system of relationships. Its system of causation will differ from the probability-distributions of modern quantum theory, perhaps by a suitable modification of the latter by means of Volterra functionals of the historical type.

I do not think that Admiral Beadnell need have any fear that my use of the adjective 'non-material', *as applied to radiation,* will be a source of any comfort to the 'metaphysicians', for, in the sense in which I used it, non-material means 'not having the same properties as matter', but at the same time something quite as real. He is quite right, however, in pointing out that this use of the adjective non-material is inconsistent with the use of the same adjective as applied to Prof. Kapp's "specification", where it means unreal, in the sense of being derived *a priori* from the dialectic of metaphysical 'idealism'.

The complementary aspects of the descriptions, namely, 'wave-like' and 'particle-like', of the behaviour of both radiation and matter in different experimental conditions were very puzzling at one time, but I think I am correct in stating that modern quantum and quantum-statistical theory has found a consistent method of predicting the macroscopic results of all such experiments without involving the assumption that matter and radiation are synonymous terms. I think that if Admiral Beadnell will refer to Heitler's recent book on the quantum theory of radiation, he will obtain a definite answer to his question such as I am not competent to give. I wish to thank him for his friendly comment and his kindly reference to my review of Prof. Kapp's book.

Optical Images formed by Conical Refraction

A PLATE of biaxial crystal cut approximatel normal to the axis of single-ray velocity has th remarkable property of forming optical images o an illuminated object held in front of it. This effec was first observed with aragonite[1] but is exhibite in a much more striking fashion by a plate c naphthalene prepared for the exhibition of conica refraction as described in a recent note[2]. Th accompanying reproduction illustrates this phenomenon. 1 and 3 reproduce objects held in front of th crystal, while 2 and 4 are the corresponding image formed in the rear of the crystal and received directl on a photographic plate. The image recorded is i every case erect and of unit magnification. Th distances of the object and of the image from th crystal faces may be independently varied fro zero up to large values.

We have investigated the explanation of this effect, using a point source as the object, and find that in every case the light reaching the image-point diverges behind it in the form of a hollow cone of rays, the angle of divergence depending on the distances of the object and of the image from the crystal faces. The image formation is thus due to a kind of generalized 'external' conical refraction which can scarcely be reconciled with the ordinary ideas of geometrical optics. Our experiences show clearly that the usual explanations of conical refraction do not go deep enough into the physical aspects of the problem.

Colour Measurement

Mr. Guild's letter[1] makes it clear that the recent conflict in views on colour measurement arises by his adopting an interpretation of the role of the C.I.E. colorimetric system which puts it outside purely physical discussion. The explanation he suggests does not, however, apply, as I have not been concerned with the public and practical aspect to which he refers. As was clearly stated[2], my remarks referred to the purely physical analysis of the phenomenon of colour, and measurement of the quantities following from such analysis: the C.I.E. system was therein referred to for what fundamentally, apart from all implication and interpretation, it actually is, namely, a conventional schematization of physical fact, having reference to certain conditions of observation, based, of course, upon averaged data but nevertheless representative in such conditions of a possible *real* observer (cf. the analogous purpose served by Listing's typical schematic eye in ophthalmology). In this sense the system forms in general a representative first-order theory. Such use of the system accords with normal physical practice, for no suggestion of compromise in form, or simplification of the phenomenon has hitherto been implied in the reduction of physical data to refer to the C.I.E. normal observer.

Mr. Guild makes no reference to this aspect of the question, but he makes it clear that, in his interpretation, the C.I.E. colorimetric system is not subject to the limitations affecting the physical theory upon which it is based and that it exists absolutely and purely by virtue of definition. A physical phenomenon can, however, only be defined by relation to the conditions in which it is observed, and the existing physical knowledge of the time: the C.I.E. quantities which Guild postulates are, therefore, in general fictitious, and the C.I.E. standard observer in this extended sense, therefore, is artificial and lacking properties relating to the important physical phenomena connected with the variation of such conditions as field size. For some practical purposes this may suffice, but the theory cannot be regarded as complete while such phenomena remain demanding explanation.

Measurement on the basis of such an interpretation is clearly not measurement of physically significant quantities, and considerations involving such an interpretation are, therefore, beyond the scope of the present discussions. My statements on the subject from the point of view of the development of colour physics remain unaffected by the statements made on such other grounds in the recent correspondence.

It is, of course, possible to maintain views on interpretation, compromise and simplification for ordinary purposes, and Mr. Guild's promised statement will be awaited with interest.

Periodicity of Refection in the Wild Rabbit

Since my previous communication on this subject[1] various fresh data have thrown new light on the coprophagy or refection rhythm in wild rabbits. Taylor[2] reported, that of a number of wild rabbits shot and examined for the presence in the stomach of soft fæcal pellets such as are re-ingested immediately, those shot in the evening contained such pellets; those shot in the morning did not. He suggested, therefore, that the rhythm in wild rabbits was the reverse of that found in domestic rabbits; the resting period of the former being during the day, naturally this would be the time when soft or 'night' pellets are produced and swallowed.

Since then I have taken careful note of the stomach contents every time a wild rabbit, which was killed at a known hour of day, came into my hands. I have also included records in which the time of death could be narrowed down to four or five hours. Recently I was able to examine fairly extensive material from a large area of woodland in Gloucestershire and this constitutes the greater part of the data upon which the accompanying table was based.

The criterion used was simply the presence or absence of soft pellets in the stomach. In 135 of the rabbits examined a note was also kept of the contents of the rectum; in only 4 cases did it contain soft fæcal pellets, whereas in 19 cases they were found in the stomach. It is clear from this that the process of formation and evacuation of soft fæcal pellets takes a comparative short time and is evidently not a process which is going on continually during the day resting period of the wild rabbit. This is what would be expected, if, as Eden[3] maintains, the production of dry fæcal pellets goes on most of the time, interrupted at certain points by a rapid emptying of the deeper part of the cæcum and production of soft pellets.

Period (G.M.T.)	No. of rabbits examined	Per cent stomachs with pellets
21 — 2 hr.	12	33
2 — 6	62	0
6 — 11	30	86
11 — 14	17	88
14 — 16	21	86
16 — 19	9	45
19 — 21	41	5
Total ...	192	

The accompanying table summarizes data from 192 rabbits. The periods are unequal because it was difficult, when collecting field data at other people's convenience, to narrow down the time of death to within the same range of time all through the twenty-four hours. The number of stomachs containing soft pellets is expressed as a percentage of the total for each period.

It is clear that at this time of the year (March 9–12) there are two periods during the twenty-four hours when refection of fæces takes place. The main period is, as Taylor suggested, during the day from 6 a.m. until 4 p.m., though it is not quite accurate to say that soft pellets are not found during the morning: it would be more accurate to substitute "late night and early morning". From 4 until 7 p.m. the rate of occurrence falls to 45 per cent and from 7 until 9 p.m. it is only 5 per cent. This drop corresponds with the normal commencement of feeding at this season. From 9 p.m. until 2 a.m. there is a smaller peak, and then again, when late night and early morning feeding commences, there is a drop right down to 0 per cent. In practically all rabbits examined at this time the stomach was crammed with fresh food.

These data are confirmed by activity records made at an experimental rabbit warren. The area was wired round with netting: the rabbits went out to feed through gates which operated mercury switches and recorded the time. Through March feeding activity showed peaks at dusk and just before and after dawn.

The apparent discrepancy between my previous observations and the observations given by Taylor[2] is explained by the fact that the morning occurrences of refection observed by me would come just at the beginning of the large day-time peak: rabbits shot during the early morning activity period would be earlier than this. The lack of observations of evening refection is probably accounted for by the process taking place inside the warrens.

These results, of course, only apply to a season when day and night are equal. In summer, when the shorter nights give less feeding time, it is possible that the rhythm may change.

A Substitute for Glycerine as a Mounting Medium

FIFTY per cent glycerine which is widely used as a temporary mounting medium for sections of plant tissues is now difficult to get. Instead, a nearly saturated solution of calcium chloride can be tried. Put excess of commercial calcium chloride in tap water, remove the slight amount of chalk with hydrochloric acid, let any bits settle and filter if necessary. This solution is rather similar to 50 per cent glycerine in viscosity, refractive index and, of course, will not dry up. At pre-war rates it is a good deal cheaper than 50 per cent glycerine. It can be used in just the same way as glycerine with such stains as iodine, Sudan III, alcoholic phloroglucin (but not alkalis or sulphates). If the bulk of the calcium chloride is removed by washing the section in water or alcohol for a moment, it can be stained and dehydrated in the ordinary way.

Simplification of Musical Notation

JEANS's great work on music is difficult for the ordinary physicist, if he knows nothing of music, and for the musician, not readily understandable, if he be unsympathetic to physics. There seems a moral to be drawn from it, however, that has been missed. It is, how can we make music simpler so that more people can play, anyhow to start with, the basic instrument—the piano.

I wonder if I shall awaken a chord in the youth of many when I say I tried like others when young, but found it just too difficult, and its difficulty lies in its notation. I maintain, in that all have been taught to read thoughts from printed paper, by virtue of conjuring up sounds to the brain as speech, so it should be simple to devise a method by which we could hit the correct notes indicated on a piece of written music with the facility we do the typewriter. The reason we cannot do this is that there is a conspiracy against us to make it difficult, and it is wrapped up with sharps and flats.

I will not go into the details why *A* sharp and *B* flat are not theoretically the same note, but due to what is known as 'equal temperament', they are in fact on the piano actually the same note. What is the point of making such a fuss to discriminate between the two, when all that can be struck is the one note?

Then comes the arch-conspiracy of writing in separate keys, when nothing you see on the paper is what you think it is. Who would ever have learnt to read an ordinary book if at the start of a chapter it was announced that it was a sad story and in a minor key, whereupon most of the letters of the alphabet were changed about, and then to find in the next chapter, when things brighten up a bit, that the letters have changed again in an entirely different way. Nobody but a thought-reader could have persevered, yet so it is with music; no one but a musician goes on with it. But the ordinary man reads his book with enjoyment, though not a student: so should an ordinary man enjoy playing the piano even if he be not a musician.

The first thing I plead for is that all music be written in a straightforward honest way, as if it were in the key of *C*, with all accidentals inserted. You could at least read it. You would find out later it was not in that key, but would that matter, as you would be playing it in the key desired and what more do you want? If we could get as far as that, it would be something, but I go further. I contend there are only twelve notes in an octave on the piano. All you want to know is which of the twelve to hit and in which octave. Surely not a very difficult problem in notation.

Here is really where a little organized common sense—sometimes called science—might bring great joy to millions. Surely such a thing is worth while trying and not beneath our dignity, but do not expect help from musicians; they revel in the mysticism of their trade union.

Quality Control in Manufacture

The note in Nature of April 11, p. 408, on "Quality Control in Manufacture", repeats an error made in the article on which the note is based. Prof. R. A. Fisher has made many notable contributions to statistical theory and practice, and his elegant analysis of variance may possibly be considered the outstanding contribution of the century, but I think he would be the last to agree with the statement made in the opening phrases of the second sentence of the note. The theoretical foundations on which the control charts for averages of samples is based have been long known, and those for control charts for measures of variability have been laid by the work of British statisticians other than Prof. Fisher.

Apart from this error, I think that by not referring to the British Standards Institution publication of 1935 on this subject, the notes may leave the impression that the technique is only just receiving attention in Great Britain after many years practice in the United States. Dr. W. A. Shewhart's visit to England in 1932 focused attention on the work proceeding at that time in some British industrial organizations and stimulated interest in it. The formation of the British Standards Institution Committee in 1933, which led to the publication of B.S.S. 600 (1935) and the formation of the Industrial and Agricultural Section of the Royal Statistical Society, were some of the results of the increased interest in the subject.

The interested reader will find on close examination that the use of statistical methods has been growing simultaneously in Great Britain and the United States, and that the development has differed in detail but not in principle. A careful study of the two documents to which reference is made (B.S. 600 *R*: 1942 and B.S.1008 : 1942) will reveal this.

Education for Culture and Citizenship

The conflict between subjective and objective biological teaching, referred to in the leading article on "Education for Culture and Citizenship"[1] and by Mr. L. J. F. Brimble[2] need not arise when the subjects of a school curriculum are more closely related, so that matters undesirable to teach from one angle can be taught from another. Such closer relationship could be obtained were education regarded as the fitting of man for his environment.

The subjects of the school curriculum would then fall into two groups: (1) man in relation to environment (the humanities), and (2) environment in relation to man (the sciences). Each group would dovetail into the other, and each subject be taught as part of a related whole, to the relief of overcrowded curricula. Environment for juniors would, of course, be the vicinity of the school, and syllabuses be based on its natural features and human activities. Even great cities provide a surprising amount of material for biological study and for that training in habits of observation and inquiry which is the root of true education. As the students get older, environment would broaden out to the whole world, and travel and research begin to play their part in education.

First Publication of the Geological Society

In reply to Mrs. Eyles's query[1], there is no reason to doubt that the pamphlet "Geological Inquiries" was issued in 1808, which is the date inscribed by Horner on his copy now in the library of the Sedgwick Museum. That it was published before the first volume of *Transactions of the Geological Society* is clear from the following extract from the Preface (*Transactions*, 1, June 28, 1811, p. v): "shortly after their establishment [Nov. 13, 1807] they [the founders of the Geological Society] drew up and distributed a series of inquiries."

FLOODS OF SEPTEMBER 1938 IN NEW ENGLAND

THE hurricane which visited New England in September 1938 is rather artlessly described in a massive volume of 562 pp. as "the greatest catastrophe since settlement by the white man"*. The loss of life was very heavy and the material damage by flood, wind and wave exceeded three hundred million dollars. The greater part of the damage was caused by flooding of the rivers resulting from heavy rain, and coming so soon after the great floods of March 1936 it caused much alarm. The U.S. Geological Survey has accordingly collected all the available information about rainfall and river-levels as a basis for the design of protective measures for the future.

The antecedent conditions were unfavourable but not in themselves dangerous. In the preceding months rainfall had been above normal, and by September 11 there was an accumulated surplus of moisture in the ground. Heavy rain during September 12–16 added to this, but though the rivers ran bank high there was no flooding. On September 16 there was even some improvement, but from September 17 onwards the weather was consistently unfavourable. On September 19 a trough of low pressure lay over New England in which moist tropical air moved northwards, giving falls exceeding 5 in. in twenty-four hours. Meanwhile a tropical hurricane was moving rapidly northwards near the coast. As a rule these hurricanes keep well to the east, but this one was diverted into the open trough of low pressure, and on September 21 moved rapidly inland towards the Canadian border. On the eastern side of the centre the winds reached hurricane force, doing widespread damage, and the rainfall was torrential, but with the passage of the centre the rain ceased abruptly. In the twenty-four hours ending at 6 p.m. on September 21, 6 in. or more fell over 1,020 square miles, and floods which, though severe, might have been manageable, burst all bounds.

Rainfall charts are given day by day and again for every twelve hours, but since the effect of flood rains is largely cumulative, greatest interest centres in the map for the whole period September 17–21. The distribution is remarkable, for while there was a rainfall of 6–10 in. in these five days over a very wide area, the greatest amounts of 10 in. to more than 17 in. were confined to a comparatively narrow belt along the hurricane track northwards from Long Island, comprised mainly within the basins of the Connecticut, Merrimack and Thames Rivers. Over an area of 100 square miles in Connecticut and central Massachusetts the rainfall exceeded 16 in., equivalent to the total average rainfall in London from January to September inclusive. On the eastern side of this belt the rainfall diminished almost abruptly, so that the coast of Massachusetts received only a few inches, but on the western side the decrease was more gradual and flooding extended for some distance with decreasing severity. In many places on the smaller streams in the central belt the crest of the flood reached levels several feet higher than any previously recorded. The tables of flood height and discharge which make up a great part of the book show instances of discharges which were only a few cubic feet per second per square mile of drainage area on September 18 and 100 cub. ft. on the morning of September 21, but had risen to 400 or 500 cub. ft. a few hours later. On the larger rivers the rise was naturally slower as various tributaries came in at different stages, but the cumulative effect was as great. Under the pressure of the water, dams and bridges gave way and the rivers spread over their flood plains, destroying roads, railways and houses; the damage is vividly shown by a fine series of photographs.

The coasts naturally did not suffer from river flooding, but they were swept by a great storm wave, which in the eastern areas coincided with the normal time of high tide and rose to heights of 10 ft. and, where the waters were heaped up in narrow channels, more than 17 ft. above the average level of high water; New York's holiday coast was devastated, scores of houses being completely demolished.

The flood problem of rivers in populous country is one of great complexity. To enable the waters to flow away freely and naturally, the flood plain should be kept unobstructed, but the life of the towns and villages depends on the river, and encroachments are hard to avoid, while it is to these low-lying settlements that the danger is greatest. Reservoirs, whether constructed specially for the purpose of controlling flood water or for other purposes, play a useful part in minimizing the rise, but if the river sweeps away the obstructing barrier and empties the reservoir, the sudden influx of stored water may add to the catastrophe; in fact, many of the curves of flood height show a double crest due to this cause. The volume of flood water depends on the absorption of the ground as well as on the rainfall; the great flood of March 1936 was magnified by the melting of the snow and by the imperviousness of the ground, which threw practically the whole of the rain-water into the rivers; by contrast in September 1938 the ground, in spite of its previous soaking, managed to absorb a good deal of the earlier rainfall, though it could not cope with the torrential downpour of the last day.

Hurricanes have visited New England before, and will doubtless do so again, but this detailed record compiled by the U.S. Geological Survey will at least provide American engineers with the data for plans to minimize, though they are unlikely to be able entirely to avert, the effects of future visitations.

C. E. P. Brooks.

BIOGEOGRAPHIC DIVISION OF THE INDO-AUSTRALIAN ARCHIPELAGO

ON April 16 and 30 a discussion was held by the Linnean Society under the chairmanship of the president, Dr. E. S. Russell, on "the biogeographic division of the Indo-Australian Archipelago, with criticism of the Wallace and Weber lines and of any other dividing lines, and with an attempt to obtain uniformity in the names used for the divisions". The following papers were contributed: Mr. J. B. Scrivenor, "Geological and climatic factors affecting the distribution of life in the Indo-Australian Archipelago"; Mr. I. H. Burkill, "A historic account of the divisions which have been proposed"; Dr.

---

* Hurricane Floods of September 1938. U.S. Geological Survey Water-Supply Paper 867, 1940.

Malcolm A. Smith, "The divisions as indicated by Vertebrata"; Dr. A. S. Corbet, "The divisions as indicated by the Insecta"; Mr. H. K. Airy Shaw, "Some general considerations from the botanic standpoint"; Dr. P. W. Richards, "On the ecological segregation of the Indo-Malayan and Australian elements in the vegetation of Borneo"; Dr. F. E. Zeuner, "The divisions as indicated by the distribution of insects in relation to geology".

The object of the discussion, in so far as it aimed at uniformity in principle, can be said to have been attained because there was a general opinion that division into biogeographical sub-regions was preferable to divisions by lines such as the Wallace and Weber lines, but no agreement was reached as to what those sub-regions should be. At the same time it was held that the Wallace and Weber lines retained some importance, but that the Wallace line as drawn by him to pass from the northern end of the Macassar Strait to the east of the Philippines should be modified so as to pass along the deep channel between Mindoro and the small islands off the northern end of Palawan. The southern termination of the Wallace line between Bali and Lombok has been criticized as unimportant by Dutch zoologists, none of whom, through the unfortunate force of existing circumstances, could take part in the discussion. It was also agreed that at the height of the Pleistocene glaciation the Sunda and Sahul shelves were dry land but that there is no precise knowledge yet how far the sea rose above its present level when the ice melted. The discussion was partly directed to considering the validity of Wegener's theory of continental drift as applied to the particular hypothesis that the Australian continental block with New Guinea as a spear-head has broken through what was once a continuous chain of islands now represented by the islands of the Banda Arc and the Bismarck Archipelago. An inquiry as to the general opinion of geologists about continental drift elicited a reply that the theory explains so much that there is a feeling that it must be true but that as yet there is nothing that can be called proof of it. It was agreed that the Indo-Australian Archipelago consists of two comparatively stable areas, the Sunda and Sahul shelves, with a very unstable area, sometimes called 'Wallacea' in between, where mountain-building is now in progress and where islands with rugged contours alternate with areas of deep sea. The Wallace line roughly follows the edge of the Sunda shelf and the Weber line that of the Sahul shelf; but the latter is drawn so as to pass on the west of the Kai Islands and on the west of Halmahera, whereas the edge of the Sahul shelf is to the east of those islands.

Mr. Burkill gave an interesting survey of proposed zoological and botanical divisions, the former following vertical and the latter horizontal lines. He mentioned doubts expressed by Wallace himself about his line and especially about the position of Celebes with regard to it, which he said ("Island Life", 1895 ed., p. 462) might perhaps with equal propriety be left out of both the Oriental and Australian regions. Weber's line was the result of tudying the distribution of freshwater fish, but had been slightly modified by Pelseneer and Merrill, while Lydekker would have placed Halmahera west f it.

The unstable 'Wallacea' is a broad transition belt n which a mixture of fauna and flora occurs. Dr. Malcolm Smith emphasized the evidence given by the re-establishment of life on Krakatau after the 883 eruption of the ease with which organisms, large and small, could have travelled by water and air from the continental areas to the islands in this belt. He said that while the Sunda vertebrate fauna is very like that of Asia, that of New Guinea is not so similar to that of Australia because climatic and geographical conditions differ to a greater extent.

Mr. Airy Shaw said that lowland and mountain floras in the Indo-Australian Archipelago may have quite different affinities with the floras of adjacent regions. Speaking of the floras within the Archipelago, he said that the lowland floras of Sumatra, the Malay Peninsula, Borneo and the Philippines are much the same, but that of Java differs from them. The mountain floras of Sumatra, Java and the Lesser Sunda Islands resemble each other but differ from the mountain flora of Borneo. Dr. Richards, as a result of his work in Borneo, thought that the Australian element has only been able to penetrate into the Archipelago where the soil is poor, and he thought that the Wallace line only holds good at all in so far as it agrees with the divisions of climatic and physical factors.

Dr. Corbet and Dr. Zeuner both dwelt on the importance of butterflies in connexion with the discussion and described the distribution of certain genera. The former proposed a division into sub-regions which he named the Malaysian, the Philippine, the Celebes, the Moluccas and New Guinea, and the Lesser Sunda Islands sub-regions. These differed from Dr. Malcolm Smith's proposal of Malaysian, Philippine, Indo-Chinese, Papuan, Austro-oriental and Australian sub-regions. Dr. Zeuner thought that the Wallace and Weber lines could not be defined biologically and that the Australian continental block is approaching Asia.

In a general discussion which followed the last paper read, Mr. Norman cited the evidence of the distribution of freshwater eels as bearing on the earlier relations of land and sea in this area. The importance of co-operation between biologists and geologists was mentioned, but one speaker pointed out that neither must rely on the other too much for proof of their theories but must rely chiefly on their own efforts.

J. B. Scrivenor.

CARNEGIE INSTITUTION OF WASHINGTON

The Year Book of the Carnegie Institution of Washington No. 40 covers the year July 1, 1940–June 30, 1941, and includes the report of the president as well as the reports of departmental activities and co-operative studies.

In his report, the president refers to the retarding of the attack on many problems on the border line between physics and biology, to implement which the construction of a large cyclotron has commenced, as well as on the new approach to human genetics, but emphasizes the responsibility of such an organization as the Carnegie Institution for preserving intact some of the more important threads of fundamental scientific research, now almost completely stopped all over the world. With regard to defence activities, nearly all the research in the Department of Terrestrial Magnetism was on Government problems, and the number of men employed in that laboratory had been more than doubled. Important work was also proceeding in the Geophysical Laboratory, the Mount Wilson Observatory and the Nutrition Laboratory.

To secure the proper integration of the combined research effort in the United States, Mr. Roosevelt has created the Office of Scientific Research and Development as a part of the Office for Emergency Management, and the president of the Carnegie Institution is the director of this Office, and many of the staff are members of its organization. The president points out that the close connexion of the Institution with the defence research effort has led to much closer contact between members of its staff and outstanding scientific men of the country, which should be of great benefit when the full normal programme is renewed.

Despite the preoccupation of most of the staff of the Department of Terrestrial Magnetism with defence research, progress has been made with its fundamental programme, and it is anticipated that the cyclotron will shortly be completed. The studies of the electrical and chemical conditions of the air at great heights are also progressing, as well as the co-ordination of magnetic, solar and upper air studies relating particularly to problems of radio transmission. Further progress in studies on photosynthesis is reported from the Division of Plant Biology, where recent research relating to the chemical mechanism of the photosynthetic process has necessitated revision of the old hypotheses in regard to the chemical interaction involved.

In the development of co-operation between the Department of Genetics and the Long Island Biological Association, a symposium at Cold Spring Harbor on the subject of the gene and the chromosome attracted a large group of scientific workers. Plans for the continuation of such co-operation are being formulated.

In the Nutrition Laboratory progress has been made in the development of instrumental technique and in co-operative studies of carbohydrate metabolism with reference to diabetes.

Interesting results have been obtained in the Geophysical Laboratory with the equipment for studying silicate minerals in the presence of water at high temperatures and pressures, such as prevail deep within the earth. The apparatus used is essentially an electric furnace within a strong closed chamber in which materials can be exposed to the action of steam at pressures of several thousand pounds and at temperatures far above a red heat. Other work has been concerned with the properties of solutions under high pressures.

FORTHCOMING EVENTS

Monday, May 18

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5 p.m.—Sir Henry Craw: "The Burma Road".

Tuesday, May 19

Iron and Steel Institute (joint meeting with the Sheffield Society of Engineers and Metallurgists, the Sheffield Metallurgical Association and the Refractories Association of Great Britain) (at the Royal Victoria Station Hotel, Sheffield), at 5.30 p.m.—Discussion on "Open-Hearth Furnace Refractories": (*a*) "Dolomite Bricks", (*b*) "Open-Hearth Roofs, including Temperature Control". (Chairman: Dr. W. H. Hatfield, F.R.S.)

Wednesday, May 20

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Prof. H. D. Kay: "The Future of the Milk Industry".

Institute of Physics (Electronics Group) (at the Royal Institution, 21 Albemarle Street, London, W.1), at 2.30 p.m.—Discussion on "Amplifiers for Measurement and Control" (to be opened by Mr. C. A. A. Wass).

Royal Meteorological Society (joint meeting with the Physical Society) (in the Physics Department of the Imperial College, Imperial Institute Road, London, S.W.7), at 5 p.m.—Discussion on "Emission and Absorption of Radiation in the Atmosphere" (to be opened by Dr. T. G. Cowling).

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Junior Assistant (male or female) to the Public Analyst—The Public Analyst, Parker Lane, Burnley (May 20).

Headmaster of the Eastbourne Technical School—The Education Officer, Technical Institute, Eastbourne (May 23).

Assistant Lecturer in Agricultural Bacteriology—The Registrar, The University, Leeds 2 (May 29).

University Chair of Biochemistry tenable at St. Thomas's Hospital Medical School—The Academic Registrar, University of London, Richmond College, Richmond, Surrey (June 8).

Instructor in Electrical Engineering at the East Ham Technical College—The Secretary for Education, Education Office, Town Hall Annexe, Barking Road, East Ham, London, E.6.

Senior Laboratory Assistant—Mr. R. W. Stott, Rugby School Science Laboratory, Barby Road, Rugby.

LABOUR AND MANAGEMENT IN RECONSTRUCTION

THE Labour Party has shown both imagination and vision in the interim report on reconstruction problems in war-time issued early in March under the title "The Old World and the New Society"* for discussion at a series of regional conferences and at the annual conference of the Labour Party being held at Whitsuntide. It seems to have grasped the relation of reconstruction to the war effort and puts the point as forcibly as it has been put by Sir Stafford Cripps, and in a brilliant introductory note to a recent P E P broadsheet on bodies in Great Britain considering reconstruction problems. In detail and in broad outlook, the report is evidence that the Labour Party is facing up to the problems of the post-war world, and the whole spirit of the report justifies the hope that an attack on the problems of post-war reconstruction may be possible on non-party lines.

Any such prospect is sure of the attention of scientific workers if only for the wider possibilities it would offer of utilizing their services in the solution of such problems and the establishment of the four freedoms. Their interest in the present report is already claimed by its reference to the importance of research and to the need for a more creative attitude on the part both of Government and of industry to science and scientific research. The report calls for the conscious and deliberate endowment of scientific research, both pure and applied, the financial responsibility for which shall be shared by industry and the State. There is no field of economic life in which the possibilities of scientific advance are not immense. Many of them are arrested or withheld from enjoyment by the motives inherent in a profit-making society, and while it may take time to liberate such potentialities from the present restricting forces, the necessary endowment of scientific research should not be jeopardized.

In the same vein, the report directs attention to the need to apply in the work of reconstruction some of the important lessons of management and industrial welfare that have been learned or reinforced during the War. The widespread failure to apply the knowledge acquired by the Industrial Health Research Board and its predecessor twenty or more years ago has been profoundly discouraging to many scientific workers. Their support should be assured for any move to secure the fuller utilization of the experience which is now being accumulated on such matters as communal feeding in factories, the organization of medical inspection and care as a normal function of management, the evolution of factory discipline based on consultation and co-operation rather than on coercion, the full use of industrial psychology in testing fitness for the job, the selection for executive posts in terms of tested competence and the proper planning of factory accommodation.

The importance of wise management, utilizing the scientific techniques which are now at its disposal as well as the increasing store of factual knowledge as a basis for policy and decisions, in reconstruction as well as in furthering the war effort, is not easily overstressed. It is one indispensable factor in removing friction and misunderstanding between management and worker and developing the spirit and practice of co-operation upon which efficiency depends. The seventh and eighth reports of the Select Committee on National Expenditure afford sufficient evidence on this point, and they show also that co-operation involves a contribution from the workers themselves. A new outlook and an unprejudiced and forward-looking mind are demanded of labour as well as of management in order that the national effort for winning the war and building the peace may attain its full power and efficiency.

---

* The Old War and the New Society: a Report on the Problems of War and Peace Reconstruction. Pp. 32. (London: The Labour Party, 1942.) 3*d*.

The hope that full co-operation between management and labour may yet be achieved and that the problems of post-war reconstruction may be approached untrammelled by the prejudices of party politics is encouraged by the views expressed almost sumultaneously by Mr. Bevin and Mr. Samuel Courtauld. Referring particularly to problems of demobilization after the War, Mr. Bevin stressed the importance of closer co-operation between workers and employers and the inevitability of greater State control. The fatal error would be to allow the desire for quick profits or the disposition towards rapid and undue expansion to distort post-war development into a disastrous boom. The controls which have apportioned resources in war economy must be maintained in order to distribute those resources in the most beneficial manner after the War ends. There must be a great national discipline as keen and efficiently imposed as that which has grown up during hostilities, until the problems of re-settlement have been worked out.

Clearly Mr. Bevin is prepared to face the unpopularity which may accompany the attempt to guide the nation along a difficult path which promises permanent recovery rather than a temporary boom. The twitterings which Sir William Beveridge's stimulating article in *The Times* has caused in the strongholds of individualism and *laissez-faire* are token of the opposition that will be forthcoming from the recalcitrant and backward-looking minority who find their private interests threatened. Mr. Samuel Courtauld's article in the *Economic Journal* of April shows, however, that there are leaders in industry as in science who are facing the future with unprejudiced and receptive minds.

Mr. Courtauld's article makes particularly interesting reading in the light of the Labour Party's report. Much of the ground covered is common, though the Labour Party's report includes colonial and international affairs in its survey. Mr. Courtauld, on the other hand, states the questions rather than gives the answers, and if he seems tentative, he is free from the flavour of dogmatism which at times creeps into the Labour Party's report.

When we have reached agreement as to the questions to be asked, we are entitled to expect some measure of co-operation in the search for the answers, and there is a striking resemblance in this respect in the programme outlined by Mr. Courtauld and by the Labour Party's report, and also by Prof. Carr in his chapter on "Britain at Home" in his recent book, "Conditions of Peace". Mr. Courtauld believes that the time is ripe for a review of the principles and bases of industry, and he points to the acceptance by industrialists to-day of the inevitableness of change, to their conscious respect for British ideals and the progressive gains of the past in which all classes have had a hand. There is also a re-awakening of conscience: an industrial career is now a *métier*, not merely a road to private acquisition. Fourthly, he notes a growth of real fellow-feeling with the lower ranks of industry, who have come to share the sensibilities and aspirations of those placed above them.

For all this, the leaders of industry are not likely to be stampeded into throwing everything overboard, for they have a firm faith in many enduring principles without which there is no possibility of sound rebuilding. There are many passages in the Labour Party's report which indicate at least some appreciation of this position, and it would be true to say that most, if not all, of Mr. Courtauld's assumptions are implicit in its own argument. Mr. Courtauld assumes, for example, that production is the most vital activity of the nation and that Government control has come to stay. No Government, he says, can tolerate the existence within its borders of an organized and completely independent power with a radius of action as wide as its own, and the same overriding principle that makes it the duty of the Government to control industrial combination applies to trade unions as developed to-day. Government bureaucracy, he holds, as it exists in Great Britain, has proved itself incapable of conducting business efficiently; it would require drastic reform to enable it to take any part in the running of business.

Mr. Courtauld assumes that labour will increasingly share in the management policy and rewards of industry and that the trade unions will long continue to represent labour. Gambling in industrial counters is a malignant disease for industry itself. The English genius for social evolution and for compromise can find a middle way between pure individualism and pure socialism which will bring the greatest attainable good to the nation and leave more and more vested interests out in the cold. Furthermore, he draws a distinction between productive industry and financial institutions which many scientific workers have voiced before, and his views on advertising and patent law as well as on financial institutions are tolerably certain to be the subject of lively debate.

We might well hope that these fundamental assumptions are sufficiently shared by the labour side of industry to induce a common approach to the broad questions bearing on the relations of Government and industry which Mr. Courtauld puts without always suggesting an answer. Fixed policy and the choice between free trade and protection, with the allied question of subsidies; Government ownership and control and the method of exercising control with the relation between industrial representation and the Government; the rights of labour, with such allied questions as their voice in control and management, family allowances, security and wages; industrial planning, both geographical and human, including technical education; the protection of consumers; and the control of speculation—these are all broad questions on which it is for the nation, and not industry itself, to indicate in advance the main lines of the policies concerned.

On all these topics Mr. Courtauld offers pertinent comments and suggestions, as well as on the highly technical questions, similarly calling for a national lead in policy, such as the taxation of industry, limitation of profits, depreciation and research expenditure; equalization of rates; patent law; and whether selling and distribution cost too much to-day. It is true that on certain points he is somewhat nebulous. He recognizes the importance of retaining the private initiative which fosters economic progress, and at the same time wishes to make Government control in the interests of the community effective. The solution he offers, namely, the appointment of Government directors, is nevertheless scarcely adequate.

The key problem of post-war economic policy is, however, fairly raised. Industrial management must be efficient; this cannot be achieved by Civil Service formulæ, and there must be communal control. The solution may well lie first in the training and evolution of a new type of Civil Servant competent in industrial and economic affairs, and second, and more important, as Mr. Geoffrey Crowther insists, in drawing a sharp distinction between those essential industries, such as food, transport, and probably fuel, which must be managed directly under the eye of the community, and those which must be permitted to develop within the usual pattern of private enterprise but also within the pattern of a decent, civilized and democratic society.

Mr. Courtauld's article is stimulating and refreshingly free from prejudice. His observations on the planning of the human side of industry as well as its geographical aspects are welcome, and it is encouraging to find an industrial leader openly expressing the opinion that no business should be allowed to employ more juveniles than it can absorb later into the ranks of full-grown workers. The elimination of blind-alley occupations is a task that calls imperatively for the closer co-operation of Government, employers and labour. It is a matter on which scientific workers may well be expected to make their own contribution, and Mr. Courtauld's observation that care should be taken not to educate people into blind alleys is one that teachers, too, should note. The comment that colleges and technical schools pay insufficient attention to their responsibility for relating the number of pupils taught to the probable demand for them is fair, if it is true that quantitative training and recruitment imply willingness on the part of the employer to forecast and estimate his requirements.

By and large, much of Mr. Courtauld's article finds its counterpart in the Labour Party's report. Recognition of the inability of an unplanned society to maintain a reasonable standard of life for many of its citizens is common ground, as are the consequences that flow from unregulated private enterprise—the restriction of production, waste of skilled man-power and failure to use the achievements of science and technology to raise the standard of life. Implicit in both Mr. Courtauld's paper and the Labour Party report is the acceptance of the objectives stated by President Roosevelt and of the establishment of the four freedoms; indeed, the whole of the Labour Party's report shows that the party has grasped the truths outlined so ably by Prof. Carr in "Conditions of Peace", and that it recognizes the strength which a reconstructive policy will lend to the war effort. Democracy cannot develop its full power in winning the War unless we begin during its course to organize the conditions which will ensure that when victory is won the great ends of life will be effectively served for every citizen.

The right note of caution is sounded both in this report and in Mr. Courtauld's address. The first aim is to win the War, and any measures now adopted must be justified first by their contribution to victory. At the same time, unless opportunities that now present themselves of destroying rather than consolidating abuses and obstructions are used, it is useless to talk of rebuilding industry or society on better foundations.

While, however, there is much indeed in the report that indicates that the Labour Party is prepared to face questions of industrial organization and the like in a new spirit and with an open mind, one grave defect mars the report. It is common ground in almost every impartial analysis of the new society that is to be established after the War that stability will depend on stress being laid on obligations rather than on rights, on services rendered to the community rather than on benefits to be drawn from it. A social order in which the four freedoms of President Roosevelt are to be embodied in a social minimum for every citizen must have as its counterpart a standard of duties and obligations which are expected of all.

It is this note that is lacking in an otherwise admirable statement. No united attack on the problems of post-war reconstruction, no non-party approach is possible in its absence. If the emphasis falls exclusively on benefits and rights, no democratic order will be established wide enough to resist the renewed onslaught of authoritarian regimes when the present aggressors have been overthrown. The essential task is to transmute into the service of peace and the building of a new order of society, that spirit of comradeship, of unselfish and strenuous endeavour that the very preservation of democracy now demands. If in the discussions that ensue on the basis of this report this note of service and duty is firmly sounded, as the open-mindedness of the report warrants the hope, it should not be vain to look further for that united attack on the problems ahead of us, free from prejudice and party restrictions, in which the resources and skill of scientific workers among others can be fully and effectively deployed, to the lasting benefit of mankind.

SPECULATIONS IN IMMUNOLOGY

The Production of Antibodies

A Review and a Theoretical Discussion. By Dr. F. M. Burnet, with the collaboration of Mavis Freeman, A. V. Jackson, Dora Lush. (Monographs from the Walter and Eliza Hall Institute of Research in Pathology and Medicine, Melbourne, No. 1.) Pp. viii+76. (Melbourne and London: Macmillan and Co., Ltd., 1941.) 8*s*. 6*d*. net.

THE introduction of complex foreign substances of high molecular weight into the tissues of warm-blooded animals often leads to the appearance of antibodies in the blood serum. The reaction of these antibodies with the substance that stimulated their appearance—the antigen—is largely specific. Immunologists have in the main confined their attention to the specificity of combination between antigen and corresponding antibody. Analysis of natural antigens and the artificial modification of protein antigens by the addition of active chemical groups to the surface of the molecule have both proved fruitful in revealing what particular configurations in the antigenic particle determine its power to induce and to combine with specific antibody. Much less is known about the origin and structure of antibodies themselves. A single injection of antigen sometimes yields a detectable amount of antibody, but its most striking effect is to sensitize the animal in such a way that a subsequent injection induces a rapid and disproportionately large output of antibody. Upon the readiness of this 'secondary response' depends the persistence of immunity in man and animals; though all detectable protective antibody has disappeared, the antibody response of the conditioned animal to later contact with antigen is immediate and effective.

Antibodies are modified serum globulins, and it appears that antibody globulin is produced in the cells of the reticulo-endothelial system, and perhaps in lymphoid tissue. In the absence of an antigenic stimulus these cells presumably synthesize the normal globulins. We have little knowledge of the origin of the normal serum proteins, and are consequently unable to speculate very profitably about that of the modified antibody globulin. The current hypothesis is an extension of Fischer's lock-and-key analogy for the specificity of combination between an enzyme and its substrate. It supposes that the amino acids destined for synthesis into globulin are specially disposed in a cell containing antigen; they are held in a pattern determined by the nature and arrangement of the active groups on the surface of the antigenic particle, and in this pattern are incorporated into the globulin molecule, which thus bears the specific impress of the antigen.

Dr. Burnet rejects this view of the antigen as a 'template' for antibody production. Not only does the type of antibody induced by a single antigen change as immunization of the animal is prolonged, but also the animal may still synthesize antibody when it is reasonable to suppose that the injected antigen has been destroyed and the cells originally stimulated by it have been replaced by their more or less remote descendants. Moreover, the 'secondary response' is often characterized by a sharp exponential rise in the curve of antibody production, which suggests a proliferation of the antibody-forming mechanism, rather than a rapidly accelerating production from an already established set of 'templates'.

As an alternative, Dr. Burnet in the first place postulates that the serum globulins are products of self-reproducing intracellular proteinases, and represent a stage in the synthesis at which the molecule has the essential structure of the enzyme itself, and is consequently stable. In this form it is presumably turned out in the circulation; in the cell, the proteinase reproduces itself fully. A similar conception has been advanced for the multiplication of plant viruses, but there is no valid reason why it should not apply to syntheses in normal cells. In the next place, it is postulated that these proteinases, in virtue of their enzymic function, come into contact with any foreign antigens taken into the cell, and are lastingly modified by this contact. There is no synthesis of a new unit in spatial contact with the antigen (the 'template' view) but a change in the atomic structure of the proteinase that allows its effectively hydrolytic action on the foreign antigen. When the antigenic stimulus is removed, the modified proteinase continues to synthesize itself, both in the original cell and its descendants, but there is a slow reversion to the original type, and the antibody gradually disappears from the circulation. A second injection o the antigen is followed by a rapid hydrolytic action by the specifically modified proteinase, which yields products of partial hydrolysis that in turn modify th proteinase further, and so lead to progressive change in the nature of the antibody.

Speculative hypotheses of this kind serve tw useful purposes. They may direct attention to the facts they purport to co-ordinate, and they may link up the field of speculation with hitherto unrelated fields of science. Dr. Burnet's speculations serve the second purpose less happily than the first. As a example, we may consider the modification of the self-reproducing proteinase by the antigen. We may assume that the proteinase exists, and that globulin is not formed by a more complex synthetic uni which is in effect self-reproducing. But the justif cation for the type of modification postulated rests on doubtful analogies with adaptive enzymes, an with the training of a bacterial culture to utiliz substances that are not normal participants in its metabolism. The adaptive enzyme, that become evident when bacterial cells are brought into contac with its corresponding substrate, bears a superficia resemblance to antibody in that it is specifically called into being by the substance on which it act but there is little evidence to support Dr. Burnet suggestion that it represents a modification of a existing constitutive enzyme. So far as is known, bacterial species possesses a finite range of adaptiv enzymes, and though peculiar conditions are require for their synthesis, they characterize the species a surely as the constitutive enzymes.

The analogy with trained bacteria is even mor remote. We are dealing here with an adaptatio that in many cases may fairly be considered as th restoration of synthetic powers lost in the evolutio of a bacterial species from an autotroph to a heter troph, and not a calling forth of a new and abnorma activity, for there is ample evidence to suggest th heterotrophs may retain synthetic powers which a not ordinarily manifest because they are quan tatively insufficient for the full needs of the organism

The review is wide, and includes original work b the author and his colleagues, particularly on th formation of antibodies in lymph nodes, and on th logarithmic phase of the secondary response. I Burnet's fondness for the pursuit of remote an sometimes misleading analogies may be overlooked, for his speculations, backed by the experimental facts that he has marshalled, will admirably serve the purpose of challenging immunologists to explain those aspects of antibody formation that are inadequately covered by current hypotheses.

A. A. Miles.

LOGICAL FOUNDATIONS OF PSYCHO-ANALYSIS

Psychoanalytical Method and the Doctrine of Freud

By Dr. Roland Dalbiez. Vol. 1 : Exposition. Transated from the French by T. F. Lindsay. Pp. xvi+ 415. Vol. 2 : Discussion. Translated from the French by T. F. Lindsay. Pp. xii+331. (London, New York and Toronto : Longmans, Green and Co., Ltd., 1941.) 40*s*. net.

IT is fitting that a critical survey of Freud's writings should appear at this time. Insistent questions are provoked by the War. We witness the spectacle of a civilized people reduced to barbarism within a ew years and wonder how this is possible. Are wars, it is often asked, simply the outcome of unconscious aggressive impulses ? How deep is the mpress that civilized living makes upon the psyche ? Are humane dispositions wholly part of ontogenesis, and can no such dispositions be transmitted genetically ? To what extent can re-education in the postwar world nullify the effects of totalitarian propaganda instilled during the impressionable years of outh, and what are the limits of variation in conduct hat the same individuals may express under diverse onditions ? No satisfactory answer to these and other urgent questions can be attempted without enlisting the aid of psycho-analysis. Indeed, it is probably true to say that without psycho-analysis, ontemporary social behaviour is unintelligible and o coherent picture of human failings and aspirations ı the modern world can be drawn without invoking ts theories, provisional though they may be.

The foundations of psycho-analysis still lie in the writings of Freud. The reader of Dr. Dalbiez's work hould therefore be led to the conclusion that the task f disentangling Freud's analytic technique from the heory with which it is interwoven and of subjecting oth technique and theory to close examination were well worth undertaking, and that Dr. Dalbiez has cquitted himself with rare competence. He brings ɔ psycho-analysis a standard of logical demonstraion that has long been painfully lacking in this field. everal chapters, particularly the one entitled "The Various Neuroses", are noteworthy for their qualities f lucid exposition.

A specially useful contribution is the systematic ttempt to relate the work of Freud to that of Pavlov. This effort to unify two independent hypoheses formulated in very different terms meets with large measure of success. Even the much-disputed Œdipus conflict is readily translated into the language f reflexology, and is shown to result from a clash etween the processes of excitation and inhibition, he genital reflex mechanisms failing to differentiate etween two similar stimuli. Dr. Dalbiez maintains hat the development of the sexual impulse reveals tself in a progressive differentiation of object. This iew is presented as more in accordance with the acts than is the Freudian notion of sexual development as a succession of perverse phases culminating in normal heterosexuality. The belief that sexual development proceeds by integration of separate responses is in line with recent experiments on aggressive impulses in certain animal species.

Mention should be made of the discussion on symbolism, which clears up many confusions in the literature. In particular, the retrospective, reductive, causal interpretation of symbolism which is adopted by Freud is contrasted with the prospective, synthetic, teleological view of Silberer.

A number of criticisms rise to mind. The size of the second volume could have been much reduced ; its matter is scarcely commensurate with its bulk. One may blame the philosophic training of the author for a number of purely academic discussions. The chapter dealing with the psychoses in the first volume can scarcely be regarded as having achieved its aim. About a third of this chapter is devoted to a criticism of Dr. de Clérambault's theories of mental automatism, an allocation of space which is surely unmerited. It is disappointing to find that aggressive behaviour is not accorded due recognition. The word 'aggression' does not even appear in the index. The world of Dr. Dalbiez seems to be the peaceful world of the philosopher, and one would gather that Freud attached little or no importance to aggressive impulses—a deduction which would be very misleading.

John Cohen.

MATERIALS AND STRUCTURES

Materials and Structures

By D. A. R. Clark. Pp. xii+384. (London, Glasgow and Bombay : Blackie and Son, Ltd., 1941.) 25*s*. net.

Practical Design of Simple Steel Structures

By Dr. David S. Stewart. Vol. 1 : Shop Practice, Riveted Connections and Beams, etc. ; a Text-Book suitable for Civil Engineers, Structural Engineers, Road and Railway Engineers, and Students at Universities and Technical Colleges. Second revised and enlarged edition. Pp. xv+184. (London : Constable and Co., Ltd., 1941.) 14*s*. net.

THE first of these two books has been written to meet the needs of students preparing for examinations in strength of materials and structures such as those in Part I of the University of London degree, Higher National Certificate and engineering institutions' syllabuses. These demand knowledge of the calculus, and the book assumes a similar standard. It is therefore disconcerting to find several pages given up to the working out in detail of the formulæ for the moments of inertia of such simple sections as form the most elementary exercises in integration. If the reader requires to be shown the detailed operations in the case of these geometrical sections, by how much the more must he need some light on the methods by which practical sections can be evaluated. From this point of view the author has not gone far enough to satisfy the needs of students at the stage indicated.

The pattern of the book is determined by its devotion to the subject of structures, and this gives it a distinct character. Instead of ranging over the aspects of strength of materials which appertain to machines, it confines itself to those concerned with structures and its examples are drawn from this branch of engineering. It is therefore to the structural engineering student in particular that it will appeal and whom it will most greatly help. He will find it a valuable medium of preparation for his profession as well as for the more immediate needs of examinations.

Following a very able presentation of the behaviour of materials under stress, there is a useful chapter on the production of metals and on the various treatments by which steel, in particular, can be improved or developed in certain desired directions. Besides familiarizing the student with the metals, this will assist him in understanding their specifications. A lengthy chapter on testing contains much information regarding the recognized tests and test-pieces, and describes various testing machines and appliances, the text being supplemented by diagrammatic sketches illustrating their principles. The latter part of the book is devoted to structures, and treats of framed structures, influence lines, deflections, suspension chains and bridges, and finally masonry. As a concise and educative statement of the theory of structures, this section can be confidently recommended to the student to whom the subject is as yet unfamiliar.

In contrast to the volume just described, Dr. Stewart's book deals with the practical design of some of the more simple structural details. In its earlier chapters it provides information regarding the rolled sections used, drawing office practice and procedure in relation to estimates and tenders, specifications and the ordering of material—all extremely useful information to the uninitiated. Equally so is the description of the template loft, the works and the machines and processes which are to be seen there.

The designs which are dealt with in this first volume of the series are of simple riveted fastenings and splices for various purposes and of beams. The complete design of a 20-ft. span gantry girder forms the tail-piece. As compared with the earlier edition, several new features have been introduced in the form of amendments to bring the text into line with the latest specifications, fresh material has been added, and an innovation is made in the arrangement of the text on the final design so that the calculations and explanatory notes are kept apart on opposite pages, thus giving a greatly improved presentation of the subject in its two aspects, instruction and example.

WORK OF PIERRE DUHEM

The Methodology of Pierre Duhem

By Armand Lowinger. Pp. ix+184. (New York: Columbia University Press; London: Oxford University Press, 1941.) 15*s.* 6*d.* net.

IN a prefatory note the author states that his aim is to provide a summary in English of the work of Prof. Pierre Duhem (1861–1916) on scientific methodology. The greater part of the book consists of extracts from his papers and from his book "La Théorie Physique", published in 1906 and 1914, with connecting passages supplied by the author. In the last chapter the author offers some criticisms.

It is rather difficult to assess the value of a book published in these conditions. At the present time there is little in it that is not familiar to workers in the subject, many of whom will emphatically accept it and others equally emphatically reject a great deal of it; to them the only question will be whether Duhem anticipated work that has been generally attributed to others. It does not appear to me that he did. His approach is substantially that of Mach, except that he does not wholly reject metaphysics; he only draws a line distinguishing it from science. But this distinction involves the rejection of "models" and explanations from science; he insists on abstract formalism. I should say that the latter is very good if it can be done, but before accepting it as a general principle I should like to see the facts of geophysics represented without the aid of the model that we call 'the Earth'. He accepts Mach's view that the whole aim of scientific theories is economy of statement. He agrees that we make inferences from them beyond the original data, and expect the results to be verified, but says that this has no logical justification and is not science. I should say, so much the worse for such a narrow logic.

There is no mention in the book of Karl Pearson's "Grammar of Science", published in 1892, which does face this problem; and I consider that any later work on methodology that omits reference to the "Grammar" is like one on gravitation that omits Kepler's laws or one on the theory of the complex variable that omits Cauchy's theorem. Duhem actually insists at a much later stage that we must accept testimony; but we could not even arrive at the meanings of words without the process that he has rejected.

H. JEFFREYS.

MAINLY ON WILD GEESE

Through the Air

Adventures with Wild Fowl, and Small-boat Sailing. By Michael Bratby and Peter Scott. Pp. 128+21 plates. (London: *Country Life*, Ltd., 1941.) 10*s.* 6*d.* net.

THIS is a reprinted account of a series of broadcasts which Michael Bratby has made, mainly upon wild geese, and there are a number of black and white illustrations by his friend Peter Scott. There are also two excellent photographs of a pink-footed goose on her nest, evidently in Iceland or Greenland, and a magnificent photograph of an Arctic hare. Unfortunately, we are left in the dark as to who took these outstanding photographs. There are two very good photographs (facing pp. 57 and 60), taken, we are told, in Icelandic waters. Judging from the icebergs the climatic conditions that season in Iceland must have been exceptionally severe, and the conditions recorded resemble, rather, Greenland or Spitsbergen. There is a most interesting account (pp. 29, 30) of a flight of blue snow geese descending on the water on migration in dense mist and being swept over Niagara Falls. Most were killed during that tremendous descent, but a few survived, and were brought to England.

Another interesting record (pp. 66–68) is of a pink-footed goose which had been shot and slightly 'winged'. This bird became very tame, a mate was provided for her, and seven years after she was 'winged' the goose nested in a flower bed in the garden and reared a family. There she lived for twelve years, and then, as circumstances had altered for her human friends, she was given away. She was less happy in her new surroundings, and being fully winged, joined a skein of wild pink-footed geese, and was not seen again.

By the way, the author is wrong when he writes of the wings of the lesser black-backed gull (p. 80) as being "as black as coal". The wings of the British lesser black back are soot-grey, but the wings of the Scandinavian lesser black back are black.

SETON GORDON.

RADIOACTIVITY AND THE COMPLETION OF THE PERIODIC SYSTEM*

By PROF. F. A. PANETH
University of Durham

ONE of the tributes paid by the Government and men of science of the U.S.S.R. to the memory of Mendeléeff on the occasion of the centenary of his birth[1] was the publication of his "Collected Works". It contains all the different tables of the Periodic System designed by Mendeléeff at various times, and so offers an excellent opportunity to study at what pace, and up to what point, the completion of the system proceeded during his life. In the first tables, which appeared around the year 1870, empty spaces were left for the elements eka-boron, eka-aluminium and eka-silicon; for eka-, dwi-, tri-, and chatur-manganese; for the rare earth elements between barium and tantalum (many of which were known but could not be assigned to definite places); for several elements between bismuth and uranium; and, to complete the last horizontal row, for a few trans-uranium elements. The atomic weight of tellurium was assumed to be 125, instead of the experimental value 128, in order to make it smaller than that of the following element iodine, 127. All these statements were equivalent to predictions. Which of them did the author see fulfilled ?

Periodic Classification of the Chemical Elements

Period	Group 1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18

Fig. 1

In 1886 Mendeléeff himself answered this question in a very original way. He had four photographic portraits mounted in a common frame, with the autographs of the persons represented and his own commentary on the back. (The second volume of the "Collected Works" contains a reproduction of this highly interesting historic piece.) The four men and their contributions to the development of the Periodic System, as explained by Mendeléeff, were : Lecoq de Boisbaudran, discoverer in 1875 of gallium (eka-aluminium) ; L. F. Nilson, discoverer in 1879 of scandium (eka-boron); Cl. Winkler, discoverer in 1886 of germanium (eka-silicon); and the Czech chemist B. Brauner, who had greatly pleased Mendeléeff by confirming by a re-determination of the atomic weight of tellurium that it actually was 125, as expected by Mendeléeff.

When in 1905, reviewing the question, Mendeléeff prepared for the last time a table of the Periodic System, scandium, gallium and germanium were filling the lowest three of the formerly empty spaces, but still none of the higher homologues of manganese could be added, and the placing of the rare earths had made but little progress ; there were now indeed twenty instead of nineteen spaces available between barium and tantalum—thanks to the addition of the rare gases as Group 0 of the System, the only really important development between 1886 and Mendeléeff's death in 1907. The atomic weight of tellurium was now assumed to be equal to that of iodine ; Mendeléeff apparently persistently refused to believe that it was even higher (as proved by the best atomic weight determinations), although Brauner himself had admitted that his earlier low value was an experimental error. The last horizontal row shows radium in its proper position and so points to a future development—the placing of the other radioactive elements and hence the conception of isotopy —which Mendeléeff did not live to see.

If to-day we resume the never-ending task of drafting a table of the Periodic System embodying present knowledge, it will take the form of Fig. 1, or some table similar to it. We are now aware that atomic number and not atomic weight defines the position of an element, and that between barium (atomic number 56) and tantalum (atomic number 73) there are only sixteen places. We have given up hope of assigning the fourteen known rare-earth elements to consecutive groups in the System, and therefore prefer to write them outside its framework. The discovery of hafnium (element 72) filled in 1922 the place of eka-zirconium ; that of rhenium (element 75) in 1925 the place of dwi-manganese. Polonium, radon, actinium *K*, actinium, and protactinium have taken their respective places in the last two horizontal rows. Only three positions below uranium are left empty, those corresponding to the atomic numbers 43, 61 and 85, that is, eka-manganese, a rare earth, and eka-iodine. Before saying more about these, it seems necessary to add a word of explanation to the assignment of an element actinium K to place 87 (eka-cæsium).

---

* Substance of a lecture delivered before the Institute of Chemistry n London on Feb. 18.

It is well known that most of the elements from thallium (81) to uranium (92) are represented by more than one atomic species, thanks to the three radioactive disintegration series which start from uranium, actino-uranium, and thorium and emit α- as well as β-particles, thus covering some parts of the Periodic System repeatedly ("Radioactive Displacement Laws"). All three series have, however, one peculiar feature in common, namely, the successive emission of four α-particles, starting from the thorium isotopes ionium, radio-actinium, and radio-thorium, respectively. As a consequence, immediately after element 90 the elements 88, 86, 84, and 82 are formed. The elements 89 and 83 are nevertheless represented in the Periodic System, because the former is produced in the actinium and thorium series before, and the latter in all three series after, the 'four α-particle run'. Elements 87 and 85, however, are missing in the three disintegration series; compare Fig. 2, in which the full line represents the actinium series in the generally accepted form.

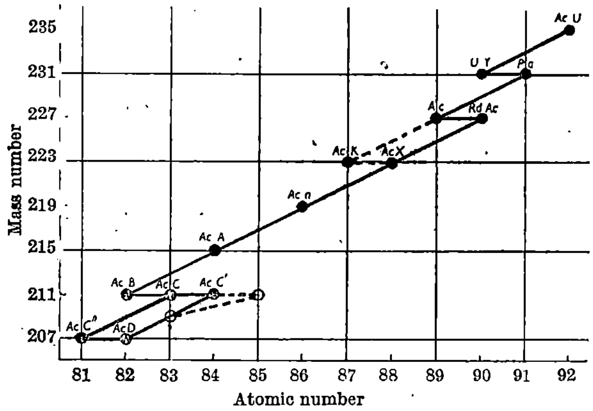

Fig. 2
RELATION OF ELEMENTS 87 AND 85 TO THE ACTINIUM SERIES.

There was always hope of finding the missing elements outside the main series as so-called 'branch products', and it was easy to predict theoretically, on the basis of the displacement laws, which atoms would have to undergo a 'dual disintegration' in order to produce the looked-for effect. If any one of the emanations emitted β-particles (in addition to their well-known α-radiation), or if either actinium or its isotope mesothorium 2 emitted α-particles (in addition to their β-radiation), the result would necessarily be an isotope of element 87. Experiments proved that neither in the uranium nor the thorium series does such a branching occur[2]. On the other hand, it was found in Vienna[3] so early as 1914 that carefully purified actinium emitted, in very small intensity compared with the activity of the main series, α-rays of the range (in air at N.T.P.) of 3·4 cm. The possibility was considered that this indicated a "dual disintegration of actinium, a small percentage of the atoms emitting α-particles, the great majority β-particles". The result of the α-radiation would, of course, be the element 87. The continuation of these researches was prevented by the outbreak of war, but three years ago Mlle Marguerite Perey[4] in Paris not only confirmed the existence of α-rays from actinium of the range observed in Vienna, but also was able to show that in purified actinium solutions to a small extent a β-radiating substance of a half-value period of 21 minutes is constantly formed; that this substance cannot be removed by the precipitation of sulphides or carbonates, but that it can be crystallized together with cæsium perchlorate or chloroplatinate. It seems most likely that this β-radiating substance with the properties of an alkali metal is the product of those comparatively few actinium atoms which emit α- instead of β-particles, and possesses therefore the atomic number 87. Of 1000 atoms, less than 10 seem to follow this path. (In the disintegration of actinium C the proportion is reversed; about 2 in 1000 emit β-particles while the rest decay with α-emission to actinium C″.) The β-radiation displayed by this element 87 would necessarily lead back to an element 88, probably identical with actinium X, in the same way as both routes starting from actinium C unite in actinium D. See Fig. 2; the abscissa shows the atomic number (that is, number of protons) of each atom, the ordinate its mass number (that is, nearest integer to the atomic weight, or number of protons plus neutrons).

Further confirmation of Mlle Perey's experiments is certainly desirable. The fact, however, that she was able to follow the decay as well as the growth of the 21-minutes substance, and the agreement of the chemical evidence with the observed α-radiation of actinium, is very assuring. As the name "actinium K" has been suggested for this new element we have inserted its symbol AcK in place 87 of our Periodic Table (Fig. 1).

There is so far no trustworthy indication of a branching of any of the main radioactive series leading to an element 85, nor has a stable form of this element been found. We must assume at present that the elements 43, 61 and 85 are missing on our earth. The regularities of the Periodic System enable us to describe approximately the properties to be expected from these elements; but especially for 85, since it is on the border line between metals and non-metals, and without a higher homologue, such predictions are necessarily vague. Fortunately for the interests of chemists who are systematically minded, there is a possibility of studying experimentally the properties even of elements which are not represented in Nature: we can try to make them, and if we are lucky enough to obtain them in a (not too short-living) radioactive form, the well-known methods of radio-chemical investigation, that is, a combination of electrometrical measurements with analytical-chemical operations, will enable us to explore their chemical behaviour even if quantities of only 10^{-10} gm. or less have been produced.

The most efficient instrument for atomic transmutation is E. O. Lawrence's cyclotron. Of the overwhelming number of nuclear reactions carried out with its help, for the purpose of our present survey, in which we intend to omit all details of no immediate interest to the chemist, we need remember only two. In many cases when an atom of atomic number Z and mass number M is bombarded with deuterons (${}^{2}_{1}D$), an atom of atomic number $Z+1$ and mass number $M+1$ makes its appearance while one neutron per atom is liberated. If the bombardment is carried out with helium nuclei (${}^{4}_{2}He$), an element $Z+2$ of mass $M+2$ may be formed, this time with emission of two neutrons per atom. The newly created atoms are mostly unstable; thus these two reactions give us the possibility of producing radioactive elements one and two places higher in the Periodic System than the bombarded elements. Their application has provided active forms of all three missing elements for chemical investigation. Here are the main results.

Element 43, Mendeléeff's eka-manganese, was obtained by bombarding element 42, molybdenum, with deuterons[5]. At least five radioactive isotopes of atomic number 43 were recognized; as their half-value periods were of the order of hours and days, a study of their chemical behaviour was possible. It was found that element 43 can be precipitated with hydrogen sulphide from alkaline and (not too) acid solutions; that it can easily be deposited electrolytically; and that its oxide is volatile. All this shows that it resembles more its higher homologue, rhenium, than its lower, manganese. It may be mentioned that the identity of one of the isotopes with element 43 could be verified even by the measurement of the K_a line of its X-ray spectrum; not in the usual way, of course, by exciting it on the anticathode of an X-ray tube, but through the spontaneous emission of this line as a consequence of the transition from a higher to a lower isomeric state of the nucleus.

For the production of element 61 both the atomic reactions mentioned above have been successfully tried. When element 60 (neodymium) was bombarded with deuterons[6], a radioactive isotope of element 61 with a half-value period of a few hours was obtained; bombardment of element 59 (praseodymium) with α-particles[7] resulted in a radio-element 61 of a half-value period of about 200 days. In this case the chemical character can be deduced with great certainty from the position in the Periodic System; element 61 must be a rare earth, of a basicity higher than samarium and lower than neodymium. It is a task for the chemist now to test this prediction with the help of one of the radioactive isotopes of 61, but scarcely anything else of interest can be expected from an investigation of invisible quantities of this new member of the rare earth group.

Far more important, for the reasons given above, is the chemical study of element 85, and it deserves special consideration also on account of its radioactive behaviour. Since the element one place lower down, polonium, is not available in sufficient quantities for a bombardment, the most promising reaction was the treatment of the element two places below, bismuth, with helium nuclei accelerated in the cyclotron. It was found that, besides others, the following sequence of reactions took place[8]:

$$^{209}_{83}\mathrm{Bi} + {}^{4}_{2}\mathrm{He} \longrightarrow {}^{211}_{85} + 2\,{}^{1}_{0}n$$
$$^{211}_{85} + {}^{0}_{-1}e \longrightarrow {}^{211}_{84}\mathrm{AcC}'$$
$$^{211}_{84}\mathrm{AcC}' \longrightarrow {}^{207}_{82}\mathrm{AcD} + {}^{4}_{2}\mathrm{He}$$

The first line shows that element 85 is formed accordng to expectations; its instability is, however, of a peculiar type, as indicated by the second line: nstead of emitting positrons its nuclei capture electrons (out of the K-shell) and are thereby transformed in atoms of a well-known natural radio-element actinium C′, an isotope of polonium. This process goes on with a half-value period of 7·5 hours. Actinium C has a much shorter period, only 5×10^{-3} ec.; it is, therefore, always present in element 85 in equilibrium quantity, and its α-radiation (range 6·5 cm.) decays with the half-value period of its parent, namely, 7·5 hours. That makes it possible to investigate the chemical properties of element 85 as though it were itself emitting the α-rays. The final product must be the same as that of the ordinary AcC′, namely actinium D, or 'actinium lead', of atomic weight 207. (It seems likely that the same final product is also reached by another way, as element 85 actually undergoes a dual disintegration, about half its atoms emitting α-particles.) In Fig. 2 we have indicated by dotted lines the way in which element 85, artificially produced from $^{209}_{83}$Bi, is changing into the natural radio-element AcC′. This example, which is not the first of its kind, illustrates well that there is no fundamental difference between 'artificial' and 'natural' radioactivity; it is therefore better to speak of 'artificially produced', and not of 'artificial', radio-elements.

Thanks to the favourable decay period of more than seven hours, the chemistry of element 85 can be thoroughly studied. The following reactions are of special interest. Mixed with bismuth it is quantitatively precipitated by hydrogen sulphide in acid solutions. Fractional hydrolysis of bismuth nitrate enriches element 85 in the first fractions; since it is known that the tendency of polonium to hydrolyse is already greater than that of bismuth, it would be interesting to compare in this respect element 85 with polonium. Closely connected with hydrolysis is the very characteristic feature of polonium of behaving like a colloid in all but strongly acid solutions; the same pecularity should be easily detectable in solutions of element 85. If this 'eka-iodine' is mixed with iodine, it cannot be precipitated, together with the latter, by silver nitrate, and it is only partly extracted by carbon tetrachloride. It can be deposited electrolytically. It is not precipitated by hydrochloric acid, in presence of lead. Its faculty of forming a volatile hydride has not yet been demonstrated conclusively; this one chemical property, however, can be predicted with complete confidence, since it depends directly on the position of an element in the Periodic Table—which must precede a rare gas by not more than four places—and is shown even by the still more metallic elements polonium and bismuth. It should be not too difficult an experiment to compare the stability of the gaseous hydride of 85 with that of HJ and H_2Po.

It is clear from the above that element 85 differs in important reactions from its lower homologue iodine and resembles more its left-hand neighbours in the VIth period. It is all the more interesting that some similarity to iodine is reported in its physiological behaviour; it is concentrated in the thyroids of guinea pigs.

It has been mentioned before that Mendeléeff, in some of his tables, reserved room for trans-uranium elements. The ease with which in many cases artificial transmutation generated elements higher in the Periodic System than the bombarded ones naturally led to experiments to create these trans-uranides. For a while it was believed that, by a neutron bombardment of uranium, radioactive elements up to atomic number 96 could be obtained. Careful chemical investigation proved, however, that most of the elements thus produced were fission products of uranium, radioactive isotopes of elements placed much lower in the Periodic Table; for example, bromine, strontium, antimony, tellurium, xenon and barium. However, element 93, that is, the one immediately following uranium, was synthesized in an active form and its chemical character studied[9]. It seems that here, too, the similarity with the preceding element, uranium, is greater than with its lower homologue, rhenium. Element 93 is, for example, not precipitated by hydrogen sulphide in acid solution, and does not possess an oxide volatile at red heat.

Finally, the question may be considered how great is the chance that the elements which so far have only been produced artificially occur in Nature. For the elements 43 and 61 it is certainly very small, for experimental as well as theoretical reasons. We have seen that the analytical-chemical properties of element 43 are very much like those of rhenium, and that there is no reason to doubt that element 61 follows the other rare earths. Now rhenium has been prepared in hundreds of kilograms, but not the slightest trace of element 43 was ever found associated with it. For element 61 a special search has been made, among others, by Auer von Welsbach, who not only had unusually large quantities of rare-earth material at his disposal but possessed also an unrivalled experience in their fractional separation; he came to the conclusion that no rare earth existed between neodymium and samarium.

To this we may add that, quite independently of these experimental facts, a general rule seems to exclude the possibility of a stable element 43 or 61. J. Mattauch[10] has directed attention to the absence, or, at least, extreme rarity, of stable isobars (that is, atoms of equal atomic weight) belonging to neighbouring elements. If two neighbours in the Periodic Table have isobars, one of the atomic species is almost invariably unstable, changing into its isobar by emission of an electron or a positron (or both). For example, ${}^{40}_{19}\mathrm{K}$ is isobaric with ${}^{40}_{18}\mathrm{A}$ and with ${}^{40}_{20}\mathrm{Ca}$; in accordance with Mattauch's Rule, ${}^{40}_{19}\mathrm{K}$ emits β-particles, thus changing into ${}^{40}_{20}\mathrm{Ca}$ (and perhaps also positrons, thereby producing ${}^{40}_{18}\mathrm{A}$, the astonishing terrestrial abundance of which has been tentatively explained by this assumption). If Mattauch's Rule is valid in the region of the elements 43 and 61, there are no stable isotopes of these two elements possible, as all mass numbers are occupied by stable isotopes of their neighbours. Element 42, molybdenum, possesses the stable isotopes 92, 94, 95, 96, 97, 98 and 100; element 44, ruthenium, 96, 98, 99, 100, 101, 102 and 104; so for element 43, the combining weight of which ought to be between molybdenum and ruthenium, no atoms with masses between 94 and 102 are available. The case of element 61 is similar.

For element 85 Mattauch's Rule makes no prediction, since from element 84 onwards no stable atoms are known. Nor are the negative results of the experiments carried out so far in search of this element conclusive; for it was generally supposed that in the course of analytical separations it would follow iodine, while we know now that it is much more like polonium and bismuth. The task of a chemist embarking to-day on a new attempt at its discovery would be facilitated not only by this knowledge but also by the opportunity of adding the artificially produced radioactive form of element 85 as an 'indicator' to his material; the α-rays, decaying with the characteristic period of 7·5 hours, would show him at once in which fraction the looked-for natural element, if present at all, is concentrated.

Even if it should be impossible to detect any of the three missing elements on the earth, it is not unlikely that they possess a transitory existence in the course of the innumerable thermo-nuclear reactions occurring in the interior of the sun and the other stars.

MOSQUITO-BREEDING IN STATIC WATER SUPPLIES

By J. F. MARSHALL, C.B.E.
Director, British Mosquito Control Institute.

IN countries such as Great Britain, where neither malaria, yellow fever nor other mosquito-borne diseases are endemic, consideration of the habits of these insects in connexion with war has scarcely ever been necessary. During the War of 1914–18, it is true, quite extensive outbreaks of malaria occurred in England owing to the fact that soldiers who had contracted the disease abroad were sent to convalesce in districts where *Anopheles maculipennis*, the chief malaria-carrier of Europe, was then (as now) particularly prevalent[1]. It may perhaps also be noted that neglect of agricultural drainage during that war led to a marked (and in some cases serious) increase in the mosquito infestation of many low-lying areas of Great Britain.

Neither of the above-mentioned contacts between British mosquitoes and war, however, attracted more than local interest; and it was only in the early part of last year, when fire-fighting authorities commenced to instal very large, open-air tanks all over the country, that any such association can be said to have become a matter of general concern. Although public knowledge regarding mosquitoes is extremely limited, most people are aware of the fact that static water is liable to encourage them: hence the appearance of these conspicuous receptacles throughout our urban areas has unavoidably given rise to considerable apprehension. It seems therefore advisable to consider, first, how far these misgivings are justifiable; and, secondly, to what extent precautionary measures can and should be adopted.

In theory, the 'control' of mosquitoes is a comparatively simple matter, owing to the fact that both their larval and pupal stages of development are passed entirely in water. Mosquitoes of the Culicine tribe (to which all but four of the British species belong) breed exclusively in static water; but those of the Anopheline tribe breed also (and in the case of many species chiefly) in running water—their larva being able to anchor themselves to surface weeds by means of certain hook-ended hairs. It thus follows that mosquito-control operations include (in addition to the obvious procedure of abolishing potential breeding-places by drainage, filling-in, etc.) the clearing and re-grading of ditches and the removal of aquatic vegetation. It frequently happens, however, that lack of time (or of funds) renders such measures impracticable, in which case an alternative method is to kill the larvæ, either by spraying oil upon, or mixing 'larvicidal' chemicals with, the infested water. In the former case the oil dissolves away a hydrofuge secretion from within the breathing orifices of the larva and then enters the tracheal system with fatal results[2]; in the latter case the larva is poisoned when it feeds. For larvicidal purposes preparations based on coal tar derivatives and introduced into 30,000–50,000 times their own volume of the infested water are most commonly employed. It is important to note, however, that water should on no account be treated with either oil or larvicide if the presence of mosquito larvæ has not been actually observed: treating uninfested water being not only a sheer waste of both time and money but also liable to destroy fish, water bugs and various other 'mosquito enemies' that natural collections of water so frequently contain.

Although all the above-mentioned operations are simple in themselves, the practical application of them is a much more complicated matter than it sounds. This is chiefly due to the numerous idiosyncracies that characterize different species of mosquitoes, notably in regard to the quality and environment of the water that they instinctively select for oviposition. (Some British species lay their eggs separately on water; others lay them separately on land liable to flooding; others stick them together during laying, so as to form 'egg-rafts'. The species *Culex pipiens*, *C. molestus* and *Theobaldia annulata* belong to the last-mentioned group.) Of the thirty species at present known in Great Britain, seven have been but rarely recorded, but the habits of the remaining twenty-three have been more or less thoroughly studied. Of the species included in the latter group, eight are known to breed chiefly in woodland pools; three, exclusively in rain-filled cavities in trees; two, almost exclusively in slow-running, weedy water; two, chiefly, and one, exclusively, in the salt or brackish water of coastal marshes—and so on. The coastal species have an exceptionally long flight-range and are consequently able to cause annoyance in localities several miles distant from their breeding-grounds.

In regard to the breeding of mosquitoes in tanks, reservoirs and other containers, it has until recently been believed that only two British species—namely *Culex pipiens* Linnæus and *Theobaldia annulata* Schrank—are at all likely to do so. Of these two mosquitoes, the former breeds impartially in either clean or foul water; the latter chiefly in water contaminated by sewage or other nitrogenous matter. Under natural conditions, *C. pipiens* rarely, if ever, bites human beings (its customary victims being birds), but *T. annulata* avidly does so. These facts indicate that tank-stored water, unless allowed to become contaminated in the manner above mentioned, is unlikely to give rise to any 'mosquito annoyance' other than the possible public apprehension that the sight (or sound) of any species of mosquito is liable to arouse.

Although, however, this assumption may still hold true where tanks in open-air situations are concerned, it would be unsafe to consider it generally applicable until the breeding habits of another British mosquito, namely, *Culex molestus* Forskal, have been more fully investigated. Both in the larval and adult forms this species resembles *C. pipiens* so closely that its presence in Great Britain remained unnoticed until 1934, when it was accidentally discovered at Hayling Island (Hants)[3]. Previous to its being found in Great Britain, the presence of *C. molestus* in other parts of Europe (for example, in France[4], Germany[5], Greece[6], Hungary[6] and Malta[6]) had already been detected, and its biology studied, by Continental and other entomologists, who considered it to be an abnormal 'variety' of *C. pipiens* rather than a separate species. The author's reasons for preferring the latter classification have been fully expounded elsewhere[7].

To say the least, the biological peculiarites of *C. molestus* are extremely striking. Of the two thousand odd species of mosquitoes at present described, less than a dozen are known to be stenogamous (that is, able to mate in a very small space) and only three to be autogenous (that is, able to lay fertile eggs without having had a blood meal before or after mating). Not only does *C. molestus* differ from both *C. pipiens* and *T. annulata* in being both stenogamous and autogenous, but it also differs from the former species in being an extremely fierce 'man-biter' whenever opportunities occur.

It was suggested that the detection of *C. molestus* in Great Britain might supply the long-awaited explanation of mysterious cases, reported from time to time, in which human beings had been fiercely bitten (notably in houses and tube railways in London) by mosquitoes diagnosed as *C. pipiens*. The accuracy of this suggestion was afterwards established by the investigation of '*molestus* plagues' occurring in houses in Hull[9]; in houses in Westminster and other Thames-side districts of London (for example, Battersea, Bermondsey, Chelsea, Deptford, Fulham and Greenwich); and in various stations of the already mentioned tube railways.

In addition to being both stenogamous and autogenous, *C. molestus* is also homodynamic (that is, able to breed at any time of the year provided that external conditions remain favourable). Possessing these three unusual characteristics, it is very easily bred in the laboratory all the year round; but, in spite of this fact, our knowledge regarding its natural breeding habits is unfortunately far from complete.

In the case of the tube railways, however, larvæ of this species were found to be heavily infesting collections of water stagnating under station platforms and between the lines. They have also been found in flooded cellars and cesspools, in underground systems of household waste disposal, in septic tanks, in cavities within a water-logged rubbish dump and in the underground tanks of a Thames-side laundry. Consideration of the above and certain other facts have led some entomologists to suggest that *C. molestus* may breed chiefly in water which, in urban and other built-up localities, is allowed to stagnate in dark, underground situations; and since, both in London and elsewhere, static water is now being stored in the basements of many houses, the possibility of *C. molestus* being thus provided with facilities for extending the range of its undesirable activities appears to be far from remote. (Should any such developments occur, the covering of ventilators, window openings, etc., to prevent gravid females of this species from reaching the water, might perhaps be deemed advisable.) It is obviously important that tanks of this kind should be kept under observation, and specimens of any mosquito larvæ seen collected for identification.

Whether even the 'man-ignoring' *C. pipiens* is likely to breed in the very large outdoor tanks that are now in use is still a matter for speculation. Should such cases occur, the question of applying oil or larvicide merely to allay public apprehension must presumably receive consideration. It has to be noted, however, that oil is extremely injurious to tanks with bituminous linings.

As already mentioned, tank-stored water that is allowed to become contaminated by sewage or other nitrogenous matter will very probably become infested with larvæ of the man-biting species *T. annulata*. Attention has, moreover, been directed to the possibility of tank-stored water becoming a suitable breeding medium for certain of our more 'countrified' species, owing, for example, to algal development or to the accidental or mischievous introduction of vegetable or other organic matter. It is, however, obviously preferable to deal with such contingencies if and when they arise rather than to adopt the spendthrift policy—advocated in some quarters—of indiscriminately treating enormous numbers of tanks on the off-chance of a few of them containing mosquito larvæ. These creatures are so easy to recognize that anyone who has ever seen one—whether in a specimen tube or a tank—can have no difficulty whatever in deciding when anti-larval measures are necessary.

SCIENCE AND WAR*

By AUSTIN H. CLARK
U.S. National Museum

FROM the earliest times of which we have a record to the present day, the history of man has been marked by constant changes in the social systems, changes that often were abrupt and violent. One form of social structure or of government has succeeded another. Small but powerful social or political units have grown by accretion or by conquest into great kingdoms or empires. These kingdoms or empires eventually have decayed or fallen apart.

Together with these frequent social, political, or economic readjustments of the past we see a constant and fairly continuous development of other forces which to a large extent are independent of transient political conditions. We note a growing interest in and understanding of the products of the earth and their uses. We also are able to trace the ever-increasing subjugation of the forces of Nature, which more and more come to be the servants instead of the enemies of man.

The greatest of all human achievements was the control and use of fire. We have no knowledge of when or how fire was first transformed from a terrifying natural phenomenon into man's most usefu servant. Second among human achievements wa the fashioning and use of tools and weapons. Th origin of the use of tools is lost in the far distan past. Then came the weaving of textiles from plan or animal fibres and the moulding of pottery vessels followed by the appearance of bronze. Not long afte the appearance of bronze utensils of various sorts the wheel and axle appeared in Asia, soon spreading to Europe.

From the Bronze Age onward the knowledge o the use of natural products and the control of natura forces have shown a fairly continuous development

Since the beginning of the present century th advance in the knowledge and understanding of th products and forces of Nature has been greater than in all the thousands of years preceding—or at leas since the subjugation of fire, the first fashioning o tools, and the domestication of animals and plants

Whether we like the idea or not, we are now living in an age, and under conditions, in which scienc plays a dominant part, and the established scientifi principles that underlie many of the most familia of our present-day improvements were unheard of or considered fallacious, no longer than a generation ago. This is self-evident to all; but the implication inseparable from a culture based ever more intensely and extensively on increasingly abstruse science are not as yet fully appreciated.

The progress that through the ages has been made in the understanding of natural phenomena and in the utilization of natural products is continuing a an accelerated pace, and will continue in the future in spite of what may happen in the next few years It may be locally obstructed, or even brought to an end, but somehow, somewhere, it will carry on.

The present struggle is no more a contest in the military field than it is in the field of science. It is quite possible to win the War on the battle front, but lose it in the laboratory. We must see to it that, so far as possible, the steady advance of science is maintained. At the present time we are utilizing to the maximum extent our scientific resources and our scientific personnel to aid in our war effort. But this is not enough. Various branches of science not of immediate military application are in the long run quite as essential for our progress and our welfare as are those forms of engineering, of physics, and o chemistry that underlie the construction and the use of modern implements of warfare. These are the many and varied types of pure science, lines of work leading to results seemingly of no importance that all too often are regarded merely as a form of mental exercise undertaken solely for the persona satisfaction and gratification of the person concerned. What we call pure science is simply a branch of science for which no economic application has as yet been found. But at any time a body of unco-ordinated facts may suddenly and unexpectedly fit into an integrated whole, to our advantage Without its advance fringe of competent workers in pure science constantly probing the great unknown and accumulating masses of data with no apparent immediate application, the broader aspects of scientific progress soon would languish. Pure science is likely to suffer severely in times like the present—in times when it would seem to be the wisest course to give it the maximum encouragement.

In the democracies, progress in any line of science is mainly dependent upon the willingness of the people to support work in that particular line which, in turn, is dependent upon popular interest and appreciation.

---

* Substance of the address of the retiring president of the Washington Academy of Sciences delivered at the 309th meeting of the Academy on January 15.

There are people who are by no means science-minded. Their attitude varies all the way from passive superciliousness to outspoken hostility. We who are engaged in scientific work, and who understand its importance in the general complex of present-day human affairs, often fail to realize how recently science has been able more or less successfully to overcome various forms of popular prejudice and to secure the favour of a very large section of the general public.

The present popular attitude towards science cannot properly be understood without some knowledge of the public attitude in the more or less recent past. I propose, therefore, to digress here in order to indicate briefly the changes that have taken place here and in England since the early days of the settlement of the United States. At that time, in the reign of Queen Elizabeth, Galileo was still a student at the University of Pisa, Tycho Brahe had just completed his observatory, and Paracelsus and Agricola only recently had died. In those days science was almost wholly included in the subject of theology, and scientific work was restricted within narrow bounds by the dogmas of the theologians.

For some time there had been a growing restiveness against the restrictions placed on scientific investigations by the theologians. This restiveness began to take the form of concerted action in the first half of the seventeenth century. As early as the reign of Charles I, about 1645, there existed in England an organization referred to by the Hon. Robert Boyle, seventh son of the first Earl of Cork, as the "Invisible College". This "Invisible College" was first suggested by Theodor Haak (or Hank), a German from the Palatinate, then resident in London. It consisted of weekly meetings at which the results of experimental work in philosophy, in its broad sense, were discussed. This was rather an unorthodox procedure for the time, but those who attended the meetings were among the ablest men of England, and included theologians as well as others. One of the theologians was Dr. John Wilkins, afterwards Bishop of Chester, who had married Robena, sister of Oliver Cromwell. Another participant was Sir Christopher Wren, who later laid down the plan for the College of William and Mary.

According to Dr. Cromwell Mortimer, "had not the Civil Wars happily ended as they did, Mr. *Boyle* and Dr. *Wilkins*, with several other learned men, would have left *England*, and, out of esteem for the most excellent and valuable Governor, *John Winthrop* the younger, would have retir'd to his new-born Colony [Connecticut] and there have established that *Society for promoting Natural Knowledge*, which those Gentlemen had formed, as it were, in *Embryo* among themselves".

Emigration to America was, however, forestalled. On November 28, 1660, the "Invisible College" became visible as "The Royal Society of London for Improving Natural Knowledge". On the Wednesday following, word was brought that King Charles II approved the design of the meetings; in October 1661, the King offered to be entered as one of the Society; and in the next year the Society was incorporated under the name of the Royal Society, the first charter of incorporation passing the Great Seal on July 15, 1661.

Although the Royal Society remained in England, both the College of William and Mary and Harvard College received considerable amounts of money from the estate of Boyle after his death in January 1691–92.

Science now began to assume a new aspect. Charles II had in effect declared that there is nothing irreligious in reporting facts. So records of observed facts and their interpretation in the light of other facts began to supersede introspection in which the aid of facts was regarded as superfluous, combined with interminable commentaries on the works of Aristotle.

Following the Restoration, science in Britain became largely an occupation of the aristocratic and the wealthy, and for the most part was followed along lines that had little or no economic application. In the public mind it came to be identified more or less completely with the aristocracy and to be regarded as partaking of the same aloofness from the general run of human affairs that characterized the social life of the upper classes. The natural result of this was that when, in the Victorian era, the champions of the lower classes began to gain a considerable following, they, or at least many of them, attacked science as one of the perquisites of the aristocracy. This attitude is well illustrated by Charles Dickens's "Mudfog Papers" published on the occasion of the first meeting of the British Association for the Advancement of Science.

Since that time science in England gradually has come more and more into popular favour. Applied science has made rapid strides and is now quite as fully developed and as highly regarded as it is in any other land. The rise in the prestige of applied science, however, has not been accompanied by any noticeable decline in the popularity of pure science, so that here we find the two types advancing side by side in more or less ideal balance. But, unfortunately, science in Britain still does not have the complete confidence of the public, and is not by any means free from neglect, disparagement, or even attack in the popular Press.

In the United States the history of science has been somewhat different. In early Colonial times scientific effort was devoted mainly to making known the natural resources of the new land, particularly the plant and animal life. But applied science early attracted the attention of the colonists. In later Colonial times applied science, especially in certain engineering branches, was systematically discouraged in the fear that the Colonies might become competitors of the mother country in the production of manufactured goods. It was possibly partly as a reaction from this suppression that after the Revolution science stood high in the favour of the representatives of the American people, its most insistent and powerful advocates being Thomas Jefferson of Virginia, Benjamin Franklin of Pennsylvania, and John Adams of Massachusetts. But it was some time before the new country was sufficiently well organized to enable the people to devote much thought to science. When they did, a spontaneous interest, taking various strange and crude forms, appeared, particularly in the agricultural areas. This crude popular science—and pseudo-science—gradually became amalgamated with the more orthodox science of the schools and colleges, and we note, especially after the middle of the last century, an enormous expansion of applied science in all forms, later very largely supported by Federal and State appropriations made possible by active and widespread interest among all the different groups in our population.

In the United States popular interest in science is twofold, arising both from the vista of economic betterment resulting from applied science, and from its appeal to the imagination. We all like to look forward to the day when we shall be even more comfortable than we are now. But we all have a non-material side. We like to get away from the hard realities of everyday life and to contemplate the unknown, and beyond that the unknowable. We all would like to know more about the world we live in. What would we find a few hundred miles down in the earth, or 20,000 feet below the surface of the sea ? We would like to know more about the stars : Are there any other worlds like ours ? And what is it like in interstellar space ? We would like to know more about ultimate human origins—indeed, about very many things concerning which our present information is vague and fragmentary. Now although popular interest in science is more general and more widespread in the United States than it is in most other countries, it tends to gravitate in these two directions, towards the directly economic and towards the mysterious. Between these two extremes lies a broad, intermediate field in which the American people as a whole takes little interest, but which is intensively cultivated elsewhere. This is the descriptive branch of pure science, the results of which are of no immediate economic import and are not mysterious.

Popular interest in science must not only be maintained, it must also be increased if we are to hold our own in the years to come, for whether carried on under Government support or in endowed institutions of learning, the full development of our scientific potentialities is dependent upon a sympathetic public attitude. In order to secure, to maintain and to increase public interest in and sympathy towards scientific work, and to convert the still disconcertingly numerous unbelievers, it is essential that we continually provide the public with news regarding scientific progress in all lines of interest to them, from both the material and non-material or philosophical points of view. Such impersonal news is especially desirable in times of national emergency.

Fortunately, in this respect the United States is in an excellent position. More and better science appears in its daily Press and other journals than in those of most other countries, and science is less frequently disparaged and denounced there than elsewhere. For this we have chiefly to thank the National Association of Science Writers, the members of which, in addition to knowing science, know the public mind and are able to present the advances in science in terms everyone can understand.

Progress in science is possible only with the support of an interested and appreciative public. It is also possible only through the efforts of a carefully selected and adequately trained personnel. This is a matter that heretofore has scarcely received the attention it deserves.

At the present time a very serious danger to our continued progress in science has arisen. This is the introduction into the Army of many young men who would be of vastly greater value to the country if they were permitted to continue their studies, or to remain in research positions. The matter is further complicated by the fact that as a rule the most valuable of these young men are those most likely to enlist on their own initiative.

After the War of 1914–18 there was a marked scarcity of able young scientific men. This was most noticeable, perhaps, in the biological sciences, thoug it was more or less noticeable in other branches a well. Many promising young men were killed. Other as a result of several years spent in the variou armies, found themselves unable to make the nece sary readjustment to scientific work. Still othe tried to readjust themselves but were only partiall successful. Breaking the thread of continuity effort between the impressionable boy in the forma tive period and the mature man cannot but resul in a certain amount of dislocation. We are reminde of the old Berber proverb :

> "Teaching boys is like ploughing earth,
> Teaching men is like ploughing rock,
> Teaching old men is like ploughing water."

There are two ways out of this dilemma. Eithe the student may be placed on a deferred list so tha he may be enabled to continue his studies uninte ruptedly, or he may be assisted in carrying on hi work, to whatever degree may be found practicabl while in the Services.

Many young botanists and zoologists would wel come an opportunity for collecting specimens an continuing their studies in regions new and strang to them. Such material as they collected could b sent home to be identified, or to be stored until thei arrival. Activities of this nature carried on in thei spare hours would go far towards overcoming tha feeling of boredom that afflicts almost everyon stationed at an isolated army post or naval base, an there is no reason for believing that these activitie would in any way detract from their military effi ciency. Not only would this work benefit the me engaged in it; it would also go far towards filling man gaps in our knowledge of the distribution of animal and plants, and of other features connected with them

In army posts and naval bases a young zoologis or botanist who spends his spare time catchin insects or pressing plants will at first be an objec of ridicule to his associates, both officers and men His situation, however, is by no means withou precedent—and most honourable precedent. It ma comfort him to realize that the world's leadin authority on the Hesperiidæ, a peculiarly difficul group of butterflies especially characteristic o America, is Brigadier General William H. Evans o the Royal Engineers, while in the Royal Navy Rea Admiral Hubert Lynes is the leading authority on a very puzzling group of small African birds. Som time ago the collections of the British Museum wer enriched by a fine collection of butterflies presente by Captain Lord Byron. Looking at the matter in a more frivolous light, is a young man using his spar time to continue his studies, and at the same tim to advance our knowledge of animals and plants, an more ridiculous than an ancient tough old sea-dog i the forecastle engaged in fine embroidery work wit delicately coloured silks, to the accompaniment o blood-curdling oaths ?

A vast amount of such work has been done by th personnel of foreign armies and navies in the past particularly by officers in the British services. I fact, at one time the United States Navy assigne interested young officers to the Smithsonian Insti tution for instruction in the collection and preserva tion of material.

Whether in its material or in its non-material aspects, progress in science is dependent upon the fostering of the scientific spirit. The scientific spirit is more than mere curiosity. It is an insatiable curiosity that impels one to learn everything that is known about a given subject, and then to go further and broaden and extend that knowledge by personal investigation and research, in spite of all difficulties and discouragements—and these are always many.

The spirit of science is inborn, though it may appear in anybody, anywhere, in any class, or group, or race. In order to develop the scientific spirit to the maximum, as it must be developed if we are to hold our place in the world of the future, we must watch for it at its inception, and whenever and wherever it is found encourage it.

STATISTICAL CONTROL OF PRODUCTION*

By DR. C. G. DARWIN, F.R.S.
National Physical Laboratory

FOR a number of years I had been interested in the general question of tolerances, first from the point of view of pure science and later in its more practical aspects. My interest in this subject was very much focused when I came to the National Physical Laboratory, where I found that work was being done on the actual verification of manufacturing and inspection gauges; this work, of course, deals with the subject in an enhanced degree—squared, so to speak, because there is not only to be considered the tolerance of the work, but also the tolerances on both the go and the not-go gauges which are to check the work.

From internal evidence of the gauge drawings, it looked as if some of the tolerances were assigned much closer than should be necessary, and I started to try to find out how they had been fixed. To accomplish this, on every occasion when I met an engineer I asked him how he decided the tolerances in his branch of the subject; I fear I bored a great many people at this time. I got a variety of answers which sometimes explained things a bit, but often not at all, and though I discussed it with quite a number of men, many of them occupying prominent places in different branches of the profession, I came away with the impression that scarcely any of them were really interested in the subject of tolerances. To exaggerate the picture which I got as the result of my inquiry, I concluded that in designing a new machine the chief engineer drew it free-hand with dimensions to the nearest inch, and sent it to the draughtsman to work out the detail to the nearest thousandth, who then gave it to his junior assistant to mark in the tolerances. Instructions were certainly always given that tolerances should be as easy as possible, but only lip service was done to them, and the junior assistant, anxious not to get himself into trouble, would, as a general rule, think of the smallest number he knew and then halve it. This is a caricature, of course, and has some of the absurdity of one, but also perhaps just a little of the resemblance. Seriously, it seemed to me that there was a defect in the habit of thought of many in the engineering profession, and that some sort of campaign was needed to inculcate in people's minds the idea that every number has a fringe, that it is not to be regarded as exact but as so much plus or minus a bit, and that the size of this bit is one of its really important qualities.

Without any very clear idea of where to catch hold of the subject, I had full intention of trying to do something about it at the time I went to the United States a year ago. There I came across the method of 'statistical control' of mass production, and it was obvious at once that this is the right approach. Similar work has been done in Great Britain too, in particular by the staff of the General Electric Company and by members of the Royal Statistical Society, and it was perhaps ill-luck that I never came across it before crossing the Atlantic; but that I did not shows that it was not very widely known. I would add that it is not by any means very widely used yet in the United States, though the use is spreading. In both countries it has been principally used in industries associated with electricity, such as the telephone industry, but I want to emphasize that it should be of even greater importance in the mechanical industries, and that it is specially applicable to a business like the manufacture of munitions in all their aspects.

One of the important points in the new method is that it gives reasoned instead of guessed values to the tolerances. I will take as an example the making of time fuses for anti-aircraft, and I am giving away no military secrets in doing so, since I shall invent the data and miss out a lot of other considerations that would really enter. Suppose that the lethal area of a bursting shell is such that, if it explodes within a tenth of a second of the set time, it will make a kill. The gunner therefore demands of the manufacturer that he make a fuse with accuracy a tenth of a second. The manufacturer works out his method, but finds that whereas it is easy to get one to a fifth of a second, he will have a lot of trouble to get to a tenth, and, indeed, he estimates that for the same effort of work and cost he could not hope to get more than a quarter as many fuses if they must have the accuracy of a tenth. Now half his shells will burst within the range I asked for and so, in fact, I shall be wise if I accept his inferior fuse, since I shall thereby get four times as many shells of which half will do what I want, and I shall therefore double the rate of killing. I need not say that I have over-simplified the business; on one side I have missed out the cost of the other parts of the shells, and on the other, I have forgotten that the gunner has uncertainties of range to consider, so that his demand for a tenth of a second is more exact than he can justify for practical use.

My example is intended to show that it is good business for the user and the maker of any article to get together before deciding the tolerances of manufacture. The user may be inclined at first to feel that in doing this he is surrendering some of his freedom of choice, but if you consider it closer you will see that this is not so. He has not got any real freedom of choice, since he must surely try to design the article so as to be as easy to make as possible, but he has foregone the quantitative information of what will in fact prove to be easy, and above all of what thing, easy to make, will be good enough for the job. I may summarize this aspect of the matter by saying that the user has tended to demand that everything should be made for him as well as possible, but he ought to want everything to be made for him as badly as possible, or perhaps not quite that, but as badly as permissible. It is in this aspect that statistical control specially gives the right information.

---

* From a paper before a joint meeting of the Institutions of Civil, Mechanical and Electrical Engineers held on April 15.

There are a good many varieties of procedure called for in the circumstances of applying statistical control. First, there are the two classes according to whether it is a quantity or a quality that is concerned. It may be a measure, say, of a length or perhaps an electrical resistance, which has to fall within certain prescribed limits; for this we can measure each specimen and record it for analysis. In other cases the test is qualitative, in that the specimen either passes a test or fails to pass—for example, a vessel is watertight or not; and even the measure of a length may fall in this class if it is tested with a gauge, so that the answer is given in the form that it passes or fails to pass the gauge. Then there is another distinction that divides either type of work into two classes. Some tests, such as a measure of length, can be applied to every article made, but other tests are destructive of the specimen; for example, the test of the force of an explosive or of the tensile strength of a bar. In this last case the test must of necessity only be done on a sample, and it is obviously important to take the sample as small as permissible. Moreover, even in the case where every specimen could be tested, there will be great economy in only doing it for a sample; so that, in fact, we may reckon that sampling is one of the main features of the process, and to determine the advisable fraction of the whole number that must be sampled is an important part of the duty of the statistician. Then again the practical problem of statistical control itself falls into two parts, for there is first the business of starting a new process and getting it into statistical control, and then the business of carrying it on later, after the control has been established. All these matters are described in the British Standards Institution publications B.S. 1008 and 600 (revised), but I shall content myself with giving a very crude sketch of a single example.

The example I shall take is based on one I learnt about in the United States, and I am intentionally leaving the details incorrect and falsifying some of the facts. I learnt about it from Colonel Simon, who has shown great brilliance in developing the methods for munitions in the U.S. arsenals. The subject was a particular type of time-fuse, and the gunners had assigned certain limits of tolerance which are described in the diagram (Fig. 1). The manufacturers all had great trouble in satisfying the demand for the longer times, so that the tolerances were exceeded both above and below, and Simon was called in to set the matter right. This he did, but to simplify the story we will imagine he had been in at the start, and describe how the process might have gone. It is first necessary to be sure that the process is 'in control', in the technical sense of the term. We take a considerable batch of the fuses, keeping them sorted according to time and place of manufacture. Group these sets (or probably samples of them) in batches of five and set the fuses at 20 sec. Time each fuse, and work out the mean of each batch and its 'range', that is to say, the difference between the shortest and longest among the five. These are marked on two charts in a way described on the British Standards Institution publication (Fig. 2). From the 'range' chart it is possible with the help of tables that have been constructed by statisticians to draw on the other a pair of limits within which the dots should fall. Perhaps they will not do so; say the dots for fuses made by one particular tool fall outside. This gives sure knowledge that something is wrong with the process—the statistician cannot say what, though I was told of cases where he could go so far as to say either that there was only one thing wrong or else certainly several things wrong. It is for the engineer to re-examine his process and find the fault. Next, of course, similar work must be done at the other fuse settings. Suppose this has been done, and that the whole system is in control, and that the accuracy is good enough for the user. After this, much less sampling is needed, but every so often a group should be taken and tested in the same way; I will not go into detail, but this sampling will nearly always give warning of pending trouble, before the trouble is so bad that the fuses would actually fail in passing their test.

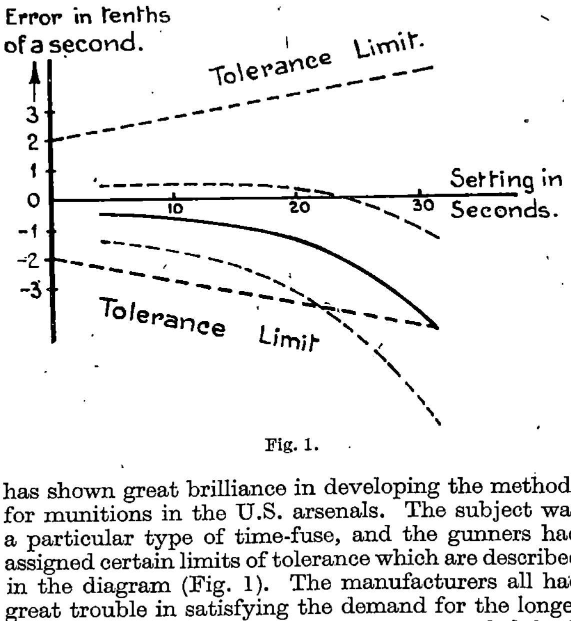

Fig. 1.

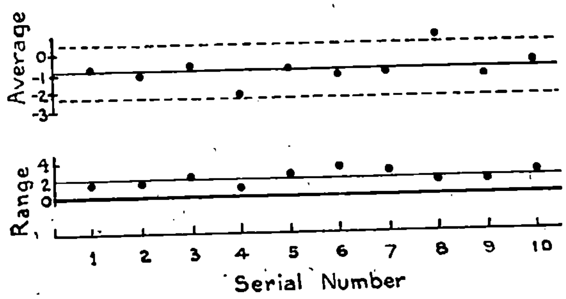

Fig. 2.

Returning to the actual history of these fuses, Simon plotted average time and 'range' for batches of five fuses at various timings of the fuse, and got the curves I show (Fig. 1) for the average timing and for the dotted lines on either side between which all values will fall. This was for the fuses of one manufacturer, and there were similar curves, some up and some down, for the others. It will be seen that the fuses mostly failed to fulfil specification at 20 sec. and above, and yet their tolerance was much finer than that which had been specified. This could be overcome in a variety of ways; for example, by regraduating the markings of the time on the fuse. The result was thus that an article which systematically failed to pass its test, was, with a quite trivial change, found to be actually better than had been asked for. I may add that as a consequence of his work Simon found that the old tests had destroyed something like twice as many of the fuses as is now necessary.

I will conclude with a few general remarks. When I first came across the method I knew it was of the greatest importance, but I doubted if the middle of a war was the time to start it. I asked this very question of two of the experts in the Bell Laboratory, and both contradicted this first thought of mine and said that it could be applied piecemeal to one process after another without delay in production. Then, as showing how quickly people could adapt themselves to it, I may recount an incident I experienced. Immediately after visiting Colonel Simon, I happened to be at Frankford Arsenal, which in peace-time was the principal factory making ammunition for the U.S. Army. As such, I expected it would be rather conservative and that it might be suspicious of new-fangled methods, and I therefore asked one of the chief colonels there what he thought of these methods, which, I may emphasize, are quite new in their application to military stores. His reply was that it seemed the only sensible way of doing the business.

Another point well worth consideration is that many works have already existing a mass of data of the kind used by the statistician, but they do not submit them to the same analysis. In such cases the change of procedure would be only slight, and a greatly improved control would be obtained by applying the statistical method.

Thirdly, the method gives information about the size of sample that should be tested. In some cases it may be inadequate, whereas in others it will be found that testing a much smaller sample would give sufficiently reliable information on the quality of the whole.

We cannot, of course, expect that the method is a panacea for all troubles, and I expect in some cases it will be tried and prove unsuitable; but I will venture the forecast that the opposite will much more often be the case, and that many processes to which at first sight it seems inapplicable will later be found to benefit greatly by the introduction of statistical control.

OBITUARIES

Mr. W. P. Pycraft

WILLIAM PLANE PYCRAFT, who died on May 1, was a well-known ornithologist and comparative anatomist. He was born at Great Yarmouth in 1868 and while a schoolboy was attracted to natural history by the wild life of the Norfolk Broads. He became a keen observer of all living things, but devoted himself specially to birds. After leaving school, he desired to follow natural history as a profession, and started as a private pupil with the curator of the Leicester Museum, where he learned the art of preserving and preparing animals for study and exhibition. In 1892 he was introduced to Prof. (afterwards Sir) Ray Lankester, who invited him to be his assistant in making preparations for the Oxford University Museum. While thus occupied he attended Lankester's lectures and demonstrations, and thus extended his outlook by acquiring a good knowledge of the structures and relationships of animals. When Lankester was appointed director of the British Museum (Natural History) in 1898, Pycraft accompanied him to London and became his temporary assistant there. Soon afterwards he joined the permanent staff of the Zoological Department of the Museum, where he remained as an assistant until his retirement in 1933. He spent his later life at Longcross near Chertsey, Surrey, in surroundings where he could continue the field observations which he had begun in early youth.
